Note: Shares refer to shares of those immigrants who report an occupation (occupation categories 1-8)
Note: This comparison excludes refugees and immigrants from certain other admission classes.

Appendix A - Data Processing Notes

The INS Public Use data tapes for the years 1977-1996 served as the source of the underlying data for this study. (Data for the years 1972-1976 were not employed because the Western Hemisphere was treated differently than the Eastern Hemisphere in these years.) These raw data were aggregated into a processed data set whose data dictionary is presented below. The aggregated data and, in some cases, further aggregations thereof were used to produce the number used in the regressions and cross-tabs presented in this study. This appendix describes this process including details such as how the structured missing data present in the data for FY80-FY83 were processed. (The INS Public Use tapes contain flaws for the years 1980-1983 that require attention.)

The data were aggregated as described in the following outline. The outermost level of the outline describes the variables appearing in the processed data set (with difference between the "old" and "new" data indicated.) The deepest level of the outline indicates the actual values the specific variable may take in the processed data set. Where necessary, additional aggregation was performed to recover the inner levels.

I. Class of Admission [10,12]
  A. Employment Based [2,4]
    1. Pre-92 categories [2]
      a) third preference (P3)
      b) sixth preference (P6)
    2. Post-91 categories [4]
      a) EB1 (E1)
      b) EB2 (E2)
      c) EB3 [2]
        (1) skilled (E3A)
        (2) unskilled (E3B)
      d) EB4 [2]

(1) A portion of EB4 which corresponds to certain formerly exempt special classes. Therefore this category is defined both Pre-92 and Post-91 (E4A).
(2) The remainder of the new EB4 category (E4B).

e) EB5 (E5)

B. Family Based [6]
1. Unmarried Sons and Daughters of Citizens (F1) P1/FB1
2. Spouses and unmarried sons and daughters of Permanent Residents. Note: Children were not distinguished from Unmarried Sons and Daughters 21 years and older prior to 1992. In these years the F2A/F2B split will be accomplished for principals based on their age and derivative immigrants are assumed to be in F2B.
a) Spouses and Children (F2A) P2A/FB2A.
b) Unmarried Sons and Daughters 21 years or older (F2B) P2B/FB2B
3. Married Sons/Daughters of citizens (F3) P4/FB3
4. Brothers/Sisters of Citizens 21 years of age or older (F4) P5/FB4

C. Exempt Immediate Relatives (IR)
D. Diversity (DIV)

II. Diversity - Is country of birth a 1996 qualified for diversity country? [2]
A. Yes (Y)
B. No (N)

III. Country of Birth [10]
A. North America (2)
1. Mexico (MEX)
2. Canada (CAN)

B. Asia and Oceania (4)
1. Philippines (PHL)
2. India (IND)
3. China (CHN)
4. Remainder (ASO)

C. Europe (EUR)
D. Africa (AFR)
E. South America (SAM)
F. Caribbean and Central America (CCA)

IV. Occupation [12]
A. Professional Technical and Kindred [3]
1. Health Professionals (H)- contains DOC, HLD, HLT, and NUR.
2. Other Professionals (P)- contains ARC, ENG, MCS, NSC, and SSC.
3. Technical Specialty (T) - contains ART, COU, LAW, LIB, SWK, TCO, TCU, TNH, and TNO.

B. Managerial, Executive (2) - contains EXC.
C. Sales (3) -contains SLS
D. Administrative support (4) - contains ASP.
E. Precision Production (5) - contains PCR.
F. Operators, fabricators, and laborers (6) - contains LAB.

G. Farming, forestry, and fishing (7) - contains FFF.
H. Service (8) - contains SER.
I. Homemakers, unknown, retired, etc. (9) - contains HOU, NOT, UNR, and STC.
J. Structured Missing (U)

V. Age [4]
A. (A1) - contains 0-19
B. (A2) - contains 20-34
C. (A3) - contains 35-64
D. (A4) - contains 65+

VI. Adjuster Detail [5]
A. New (NEW)
B. Adjuster [4]
1. H1 [2]
a) H1A- registered nurse as indicated by admission class RN6 or RN7 (H1A).
b) H1B- other H1 category (H1B).
2. L1 (L1)
3. Others (OTH)
C. Structured Missing (UUU)

VII. Principal/Derivative [2]
A. Principal (P)
B. Derivative (D)

VIII. Gender [2]
A. Male (M)
B. Female (F)
C. Missing (X)
D. Structured Missing (U)

IX. Fiscal Year

To produce the processed data set, we processed the files into an intermediate format that adds two pieces of information to the above: a registered nurse (RN6/RN7) admission class and an age indicator. These fields are used to produce the H1A/H1B and, in pre-92 data, the F2A/F2B distinctions as described above. The additional fields are then removed. Some important notes regarding the H1A/H1B and F2A/F2B split appear later in this appendix.

Distribution of the Structured Missing Data

This section describes the technique used to distribute the structured missing data in the occupation, sex, and adjuster detail variables caused by structured missing data for fiscal years

1980 through 1983. Because of concerns about data strength at the fine level of detail provided by this module, a straightforward technique of distributing the structured missing data has been chosen. To ensure that the data set remains consistent when examined in less aggregated views, we have applied the proportions determined at an aggregate level to the highest level of detail provided.

Consider a module which contains two variables affected by the structured missing data: sex and intended state of residence. Sex and intended state of residence are not relevant in the current study, but they serve to illustrate how the data were treated. The distribution procedure is described graphically in Figure 1. The structured missing data are indicated by the number in the intersection of the structured missing values for sex ('U') and state of intended residence ('UU'). These data are to be distributed into the desired categories for the sex and state. The structured missing data are distributed into the shaded region of Figure 1, which includes all sex/state pairs. On a fiscal-year basis the proportion of missing data that should be allocated to each sex/state pair is determined by dividing the total number of records for that tuple prior to distribution by the total number for all destination pairs to distribution. The data are then distributed at the finest

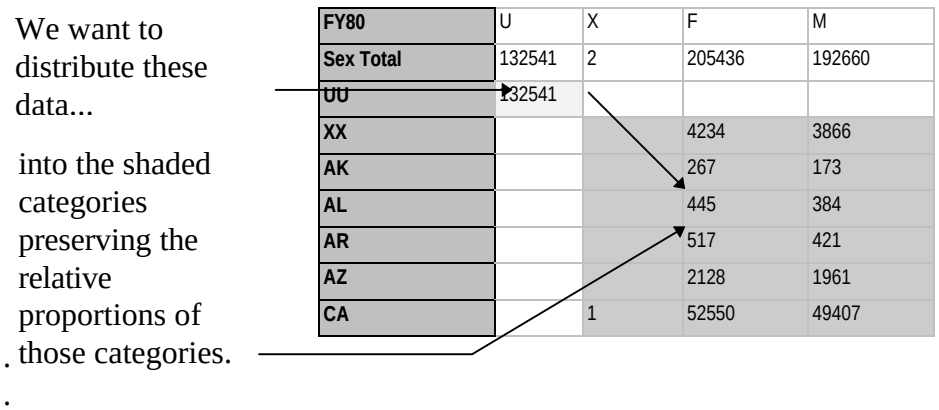

Figure 1: The distribution procedure.

level of detail provided for the module as follows. For each combination of the variables unaffected by the missing information, a table analogous to the one in Figure 1 is formed. Within that table, the structured missing is distributed to the destination pairs in the shaded area according to the proportions determined at the fiscal year level in Figure 1.

Performing the procedure in this manner ensures that the data for each fiscal year are consistent with the overall proportions in the data unaffected by the structured missing data while providing data at the level of detail required by this study. As a side effect, the data after distribution for the years FY80-FY83 include numbers that have a fractional part. This is necessary to ensure that totals after distribution agree with those prior to distribution.

As a check on this procedure, one should observe no change in the category totals for variables other than those affected by this problem. The relative proportions of each category (disregarding the structured missing category) should be the same before and after distribution.

For the processed data sets, the sex, occupation, and adjuster detail variables are those affected by the structured missing data problem.

The H1A/H1B split

The nonimmigrant class of entry field in the INS Public Use data records the most recent entry class for immigrants adjusting their status. The entry class H1 indicates a "Temporary worker of distinguished merit and ability." Beginning in 1992, the documentation indicates that the class H1 is divided into H1A for registered nurses and H1B for "temporary worker with 'specialty occupation'."

The manner in which the post-92 split is recorded in the Public Use data sets is not clear. For 1992 and 1993, the indicated codes are H1A and H1B. Since the field is has only two

characters, there is no distinction. In 1994 and later, the documentation indicates that H1A is coded as S8 while H1B is coded as H1. In these years where the distinction is clearly made in the documentation, the number of immigrants coded as H1A is negligible.

The admission class codes corresponding to H1A are RN6 and RN7 which appear in years 1990 and later. To use this information, the admission codes RN6/RN7 are mapped to a separate value of the admission class variable (namely RNE). The adjuster detail is recorded as H1 rather than making the H1A/H1B distinction. In a post processing step, the immigrants whose adjuster detail is H1 are assigned to H1A if their admission class is RNE and H1B otherwise.

The FB2A/FB2B split

Under IMMACT90 the former second preference class became the second family based preference class: FB2. This preference class is for spouses and children of legal permanent residents. IMMACT90 further distinguishes between FB2A containing spouses and children under the age of 21 and FB2B containing unmarried children 21 years of age and older.

The admission class code appearing in the Public Use Data for the second preference class does not distinguish between children under 21 and those 21 and over. To facilitate comparison between the pre-92 and post-92 data, the following procedure was used. For immigrants whose admission class was that of a child of a legal permanent resident, the age field was examined. Those under 21 were assigned to FB2A while those 21 or older were assigned the FB2B. For immigrants whose admission class was that of a derivative of a child of a legal permanent resident, there was no way of selecting FB2A or FB2B. All such derivatives were assigned to FB2B. In effect, the FB2A/FB2B split was not made for derivatives and this fact is reflected in the analysis.

The estimation procedure

The estimates are based on regressions from fiscal years 1977 through 1991. Simple numerical regressions are appropriate for the exempt categories, but would result in estimates for 1995 and 1996 which exceed certain caps in the old law such as the 27,000 limit for the third (P3) and sixth (P6) preference classes and the 80% limit on restricted family based (FB) immigration. In an effort to reflect the anticipated effects of these caps, the estimates were produced from four separate regressions: P3, P6, FB, and exempt.

The division of a group's immigrants into the P3, P6, FB and exempt categories is based on admission class. P3 and P6 each correspond directly to a value of the admission class variable. FB is the aggregation of the F1, F2A, F2B, F3, and F4 values of the admission class variable. The exempt category is the aggregation of IR, E4A, and RNE (recall that E4A was numerically exempt under the old law.) The remaining categories either do not appear in the historical portion of the data (the DIV and remaining "E" classes), or are excluded from the analysis (the REF and "X" classes.)

For the P3, P6, and FB categories regressions are performed on the share of P3, P6, and FB immigration associated with the group being estimated. For the exempt category a numerical regression is calculated. The raw estimated shares of P3, P6, and FB and the number of exempt immigrants are then estimated for 1995 and 1996. Any negative raw shares or numbers are set to zero. Then the shares are scaled to sum to 1. The estimate for a given group is then the sum of the its exempt estimate, 27,000 times its estimated P3 share, 27,000 times its estimate P6 share, and 216,000 times its estimated FB share.

The Mapping Used for Aggregation

This section describes the mapping used to aggregate the INS Public Use data into the process data sets. The utility used to perform the aggregation uses configuration files which describe how the data appearing in the Public Use Data are to be mapped into the desired variables. The appropriate portions of these configuration files are reproduced below.

Admission Class

```

Note: The admission class variables assigns all possible admission class codes to some category. In addition to the categories described in the data dictionary and the RNE class used for

H1A/H1B, there is a refugee class REF and several special classes indicated by the first letter X. The REF and "X" classes are not included in any of the tables. The F2X class lists admission categories which are F2B after FY91 but are ambiguous prior to FY92. The previous section describes how this category is used.

I. OVERVIEW

This report was prepared by The Lewin Group for the U.S. Commission on Immigration Reform. This report is based on findings from a survey of key informants in five states (California, Florida, Illinois, New York and Texas) conducted to determine the effects of federal changes to welfare policy as a result of the enactment of the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 (Public Law 104 –193, PRWORA). The survey, funded by the John D. and Catherine MacArthur Foundation, focused on the impact of changes to the following federal programs: food stamps, Supplemental Security Income (SSI), Temporary Assistance to Needy Families (TANF), and the Medicaid program (with the exception of emergency medical services), as well as on changes to state and local programs. Interviews were conducted from April through June 1997. Survey findings were updated through July 24, 1997. An executive summary and five detailed state reports accompany this overview.

This overview summarizes findings from the five state survey in the following areas:

Provisions of PRWORA that apply to immigrants

Political environment and state decisionmaking regarding PRWORA

State and local implementation of PRWORA

Impact of welfare reform on state and local governments, local economies, health and social service providers, and immigrants

Provisions of PRWORA

In August 1996, the 104th Congress of the United States passed historic welfare reform legislation that has had enormous consequences for states. Among the changes contained in the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 are specific restrictions on welfare programs and federal public benefits for immigrants. Title IV of PRWORA sets forth new requirements on the states to discontinue benefits and deny eligibility for federal, state and local welfare programs to specific classes of immigrants, including qualified immigrants, non-qualified immigrants, and illegal immigrants.

Title IV of PRWORA intersects with federal immigration law (i.e. Illegal Immigration Reform and Immigrant Responsibility Act of 1996), particularly as it relates to the designation or determination of immigration status. States are now required to understand the intricacies of immigration law in order to process applications by immigrants for welfare benefits.

Political Environment and State Decisionmaking Regarding PRWORA

In order to respond to the Welfare Act, states are required by their constitutions and by administrative practice to make a host of legislative and policy decisions with respect to the various federal, state and public benefits that immigrants receive. This is a challenging task because the criteria established in PRWORA for denying and limiting benefits to immigrants

are not uniform across programs.

Furthermore, despite the enactment of PRWORA, there is still a high level of uncertainty at the federal level surrounding immigrant eligibility for SSI and Medicaid. States are faced with the task of responding to the immigrant-related provisions of PRWORA in the absence of final decisions around major issues (e.g. whether SSI benefits will be restored for all or a fraction of legal immigrants) at the federal level.

As part of their response to PRWORA, many states and localities have legally challenged the denial of benefits for immigrants and are strongly advocating that the federal government reassumes its responsibility in this area. States argue that since they are not responsible for "immigration policy", they should not be faced with the responsibility of having an "immigrant policy", i.e. determining whether immigrants may receive benefits and paying for those benefits.

There is consensus that the objective of reducing federal responsibility for immigrants under these provisions will result in an unprecedented cost transfer to the states. In turn, some states will transfer liability for the costs to localities.

States are currently making complex and unprecedented decisions regarding federal programs in three areas: (i) immigrant eligibility decisions, i.e. whether immigrants should be covered and which types of immigrants should be covered; (ii) the level of benefits to be offered to immigrants; (iii) administrative decisions, i.e. whether to create new state programs or reform current programs to serve immigrants.

State and Local Implementation of PRWORA

The criteria for denying and limiting benefits to immigrants in PRWORA are not uniform across federal programs. The lack of uniformity and the complexity of program designs create a significant administrative burden on states to fashion program-specific eligibility changes, including management of information and the development of new tracking and monitoring systems for all affected programs.

Among the five states we surveyed, there is considerable variation in the extent to which decisions have been made. The legislative sessions in Florida, Illinois and Texas have ended. On the other hand, in California and New York, the legislatures are in session and there are still many uncertainties. In this section, we present an overview of the legislative and policy decisions that these five states have made through this point in time. States continue to debate about how to respond to the immigrant provisions of PRWORA. When the federal budget is approved, states may have to both reconsider their positions and evaluate issues they have not addressed yet. Additionally, once PRWORA is fully implemented, states will have to confront its impacts on immigrants.

Among the five states in this study, there is a wide range of responses to the immigrant provisions of the Welfare Act. Texas appears to be at one end of the spectrum. This state seems to be "in denial" of the devastating effects that PRWORA will have on the immigrant

population. On the other hand, Illinois falls on the other end of the spectrum, having already made several important decisions regarding immigrants. California, Florida and New York fall between Texas and Illinois with regard to reaching consensus around immigrant eligibility and program changes necessary to replace benefits for immigrants.

States are making decisions about eligibility for three major types of immigrants: qualified immigrants (as defined by the Welfare Act) who entered the country before the enactment of PRWORA (i.e. August 22, 1996), non-qualified immigrants, and legal immigrants who entered the country after the enactment of the Act (hereinafter referred to as new immigrants). State decisions concerning the four main federal programs are summarized below.

SSI: Only Illinois has decided to replace SSI for a fraction of qualified immigrants (i.e. those who were receiving benefits prior to August 22, 1996). Similarly, only Illinois will replace SSI for a fraction non-qualified immigrants--it will cover those individuals who were receiving benefits prior to the enactment of the Act. No state has decided to replace SSI for new immigrants.

Food Stamps: No state has decided to replace food stamps for qualified immigrants who entered the United States before the enactment of PWRORA, non qualified immigrants or new immigrants.

TANF: All states in the survey have decided to cover under TANF qualified immigrants who entered the country prior to August 22, 1996. No states have decided to cover non-qualified immigrants or new immigrants (during the five-year federal ban) for TANF at state cost.

Medicaid: All states in the survey will cover pre August 22, 1996 qualified immigrants under their Medicaid programs. However, no state will cover post August 22, 1996 qualified immigrants or new immigrants at state cost.

In addition to making decisions about immigrant eligibility, replacement of programs for immigrants and the respective level of benefits, states need to develop systems that track information on immigrants. Currently, states rely on the Systematic Alien Verification for Entitlements (SAVE) Program, a single federally-developed information system that can provide information on immigrant status. This is an inter-governmental information-sharing service for agencies and institutions that was developed pursuant to Section 121 of the Immigration Reform and Control Act of 1986 (IRCA). However, states now need information systems that can track immigrant categories and exemption criteria as defined in the Welfare Act. States are currently waiting for the U.S. Attorney General to develop verification criteria and procedures, and then they will have a year to make their systems conform to the new guidelines.

Impact of welfare reform on state and local governments, local economies, health and social service providers, and immigrants

The effects of the immigrant related provisions of the Welfare Act will be far reaching. State and local governments will face new responsibilities, an unprecedented cost transfer from the

federal government, and complicated administrative decisions. State projections of the number of immigrants who will become ineligible by type of public program apply only to current caseloads. Neither the states nor the federal government has the capacity at present to project the number of qualified, non-qualified and new immigrants who may need assistance but will not be eligible for public benefit programs in future.

The number of current recipients who will lose benefits as well as the cost to the states of losing those federal funds is significant. In California, 345,000 immigrants will lose food stamps; and 243,720 will lose SSI. In Florida, 97,658 immigrants will lose food stamps; 54,000 will lose SSI; 503 will lose TANF; and 3,062 will lose Medicaid. In Illinois 39,000 immigrants will lose food stamps; 22,000 will lose SSI; 1,698 will lose TANF; and 2,379 will lose Medicaid. In New York, 130,000 immigrants will lose food stamps; and 80,000 will lose SSI. In Texas, 140,937 immigrants will lose food stamps; 34,892 will lose SSI; about 37,061 will lose the state optional Medicaid benefits and 33,725 will lose SSI-linked Medicaid benefits. For those states that provided estimates, the loss of federal funds due to the immigrant provisions of PRWORA will be considerable. Under the Welfare Act, the most significant financial loss to the states will be the loss of SSI and food stamp funds. For food stamps and SSI, Florida will lose nearly $311 million per year, while Illinois and Texas will lose about $150 million each.

Local economies will be seriously affected by the direct loss of benefits as well as the indirect economic impact associated with diminished household incomes, purchasing power and workforce productivity.

Community-based social service and health care providers are likely to face an increased demand for their services as immigrants are denied public benefits. Whether the financial and structural capacity of these providers will be sufficient to offer a safety net to immigrants remains to be seen. Providers are also concerned that immigrants, qualified and nonqualified, may not seek necessary medical care due to the fear of being reported to the INS or fear of jeopardizing one's chances of obtaining citizenship. These fears could pose a serious health problem to the states and localities if immigrants do not receive care for infectious or communicable diseases like tuberculosis.

Immigrant families will be the most negatively impacted by PWRORA. The effects on immigrants include fear and confusion, diminished household incomes, increased food and housing insecurity, reduced access to health care and other social services, and changing incentives regarding naturalization, assimilation and family reunification strategies. The weakening of immigrants' socio-economic status and well-being will have a detrimental effect not only on immigrants themselves but on those U.S. citizens who are members of immigrant families and households as well as on communities where immigrants constitute a substantial fraction of the population, work force and social fabric.

II. INTRODUCTION

In April 1997, The Lewin Group received a grant from The John D. and Catherine T. MacArthur Foundation to conduct a survey of key informants in five states to determine the effects of federal changes to welfare policy as a consequence of Congressional enactment in 1996 of the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 (Public Law 104 - 193). Lewin also received funding from the U.S. Commission on Immigration Reform to prepare a report summarizing the findings from the five state survey.

The states included in the survey are California, Florida, Illinois, New York, and Texas. The number of immigrants residing in these five states collectively represents approximately 75% of the total number of immigrants currently living in the U.S.

This report summarizes the findings from the five state survey. Accompanying this Executive Summary are separate state reports which provide detailed findings from each of the states studied. Also attached in separate volumes are appendices for each of the states that include official documents, research papers, and other supporting materials that describe legislative, judicial, administrative, and other findings or activities outlined in each of the state reports.

This Executive Summary is organized into the following sections:

Project Purposes and Methods

State Policy Options

State Decisions and Actions

Actual and Expected Impacts on Immigrants

State Efforts to Monitor Impacts

Conclusion

Appendices

III. PROJECT PURPOSES AND METHODS

In August 1996, the 104th Congress of the United States passed historic welfare reform legislation that has had enormous consequences for states. Among the changes contained in the Personal Responsibility and Work Opportunity Reconciliation Act of 1996, (hereinafter referred to as PRWORA or the Welfare Act), are specific restrictions on welfare programs and federal public benefits for aliens (hereinafter also referred to as immigrants). Title IV of PRWORA (See Appendix I) sets forth new requirements on the states to discontinue benefits and deny eligibility for federal welfare programs to specific classes of immigrants, including qualified immigrants, non-qualified immigrants, and illegal immigrants. (Appendix I)

Title IV sets forth the basis of national policy concerning welfare benefits for immigrants including specific restrictions and exceptions regarding eligibility for federal benefits; eligibility for state and local benefits; attribution of income and affidavits of support for immigrants establishing eligibility; general provisions regarding verification and communication between states, local and federal authorities regarding immigrants and law enforcement; conforming amendments related to assisted housing; and earned income credit denied to unauthorized employees. A brief summary of the discontinuation of benefits by federal and state program for specific classes of immigrants is provided in Appendix II.

In its entirety, Title IV intersects with federal immigration law (i.e. Illegal Immigration Reform and Immigrant Responsibility Act of 1996), particularly as it relates to the designation or determination of immigration status. States are now required to understand the intricacies of immigration law in order to process applications by immigrants for welfare benefits. Currently, even the description of who is a "legal, qualified alien" creates confusion among many state workers unfamiliar with conditions surrounding entry to the U.S. by non-citizens and the role of the Immigration and Naturalization Service in the determination of immigration status. For qualified aliens, the distinctions drawn among asylees, parolees, refugees, persons with deportation withheld, and determination of minor children suffering abuse or cruelty and in need of welfare benefits altogether create ample opportunity for dismay and confusion at the local level of welfare program administration.

In addition, provisions of PRWORA regarding new eligibility requirements for immigrants requires substantial documentation by the applicant to establish all of the requirements, including residency and income provisions. One particular section of the law requires the attribution of sponsor income and resources for aliens with sponsorship. These requirements require significant understanding of immigration law and procedures and also impose new requirements to review the income and resources not only of the alien but of his/her sponsor which states have rarely performed.

Practically, states report that the enforcement of Title IV of PRWORA creates new types of work to determine an applicant's immigration status for which they are unprepared and untrained. State respondents also report that the type of work required to process applications for benefits now borders on the exercise of federal powers regarding a determination of an individual's immigration status. This intersection with federal responsibilities concerns the states and will continue to be an issue for states and localities.

Nearly one year since the passage of PRWORA, governors, legislators, agencies, interest groups, and citizens in each of the states are struggling to come to grips with the complexity of the federal law, the interaction of provisions in PRWORA with changes in federal immigration law, the range of policy and program alternatives available to the states to respond to PRWORA, and the expected impact of policy and program changes on immigrants.

Study Questions

The Lewin Group was commissioned to conduct a phone survey of key informants in five states with the highest proportion of resident immigrants to determine the impact of federal welfare policy on immigrants, including attention to impacts at the local level. The main study questions were as follows:

1. What changes are states planning in response to federal policy changes that discontinue immigrants from specific federal programs and federal/state programs?

2. How are counties and service providers responding to the federal and state welfare reforms?

3. How will the state and county welfare reforms affect the costs to states, counties and providers, particularly with respect to substitution of funds for withdrawn federal payments, and also with respect to other social (i.e. human) costs?

4. What are the problems that states, counties and providers report they will face in responding to welfare reform that were previously unforeseen by government officials?

5. What distinctions, if any, are states making to determine eligibility for welfare programs under their reforms with regard to an individual's immigration status, age, disability level, or employment status?

6. What are the direct effects of the policy changes, including health care delivery (access to care, payment for care, cost of care, and quality of care) for immigrants at the community level?

7. Are there state and local plans to monitor and assess the impact of policy changes?

Key Sources and Interviewees

Lewin developed a list of key informants in each of the states, drawing from several areas of the public and private sectors: government officials at the state and local levels charged with implementing state welfare reforms, service providers, research organizations, and advocacy groups. The officials contacted included key staff to Governors, Special Assistants on Welfare Reform, sponsors of key state legislation, state budget officers, agency heads in health care and welfare, legislators and legislative staff, state Attorneys General, County Commissioners, Boards of Supervisors, and other local officials charged with planning and executing local-level reforms.

Lewin initially contacted between 35 and 125 individuals in each of the states, depending on the size of the state, number of localities with significant immigrant populations, and the degree of local involvement in shaping state responses to the federal welfare changes. From the over 350 initial contacts, we developed about 200 key sources and conducted about 100 full interviews to produce the state reports. Key sources and interviewees are listed in Appendix III.

Lewin developed a structured interview protocol to guide each of the interviews. The protocol was sent in advance to each interviewee or group of interviewees, where we had multiple informants participating in a single interview (Appendix IV). Because of the complexity of the issues, the evolving nature of state decisionmaking and action in the implementation of welfare reform, and the uncertainty posed by ongoing federal budget negotiations concerning retention of certain key provisions of PRWORA affecting immigrants, informants had a need to speak well beyond the allotted time. In most cases, the interviews exceeded 60 minutes, some requiring follow-up interviews to complete the interview protocol and to secure additional referral sources.

Respondents welcomed the project effort and were extremely generous with their time, referrals, insight, and advice. A number of individuals contacted expressed interest in the study but declined to participate. Most of these non-respondents stated that since the status of decisionmaking was still in flux in their respective states, they did not want to engage in speculation or conjecture as to what the ultimate legislative decisions would be. Responses from each of the interviews were synthesized and are contained in separate state reports. The outline for each of the state reports is provided in Appendix V.

The following sections summarize findings from the state interviews. This report attempts to capture the high-level commonalties among the states and report on the significant differences with regard to decision processes, policy frameworks, program options, implementation of state and local decisions regarding welfare reforms affecting immigrants, and impacts on individuals and communities. Detailed state reports are attached to this Executive Summary. The state reports include findings from the many interviews conducted for each state and also include official records and proceedings describing the legislation and administrative procedures states have adopted or intend to adopt to implement welfare reform at the state and local level of government.

IV. STATE POLICY OPTIONS

In order to respond to the Welfare Act states are required by state constitutions and administrative practice to make a host of legislative and policy decisions with respect to the various federal, state and public benefits that immigrants receive. Various reasons why these changes pose challenging and protracted deliberations are discussed below.

The criteria established in PRWORA for denying and limiting benefits to immigrants are not uniform across programs. For example, food stamps and the Supplemental Security Income (SSI) program, which are entirely funded by the federal government, have been discontinued for legal immigrants, including qualified immigrants, with the exception of five categories of immigrants. For Temporary Assistance for Needy Families (TANF) program -- now a block grant according to PRWORA -- and Medicaid -- still an entitlement program funded by both the federal and the state governments -- states have the option of continuing to cover qualified immigrants who entered the United States before August 22, 1996.

Despite the enactment of PRWORA, there is still a high level of uncertainty at the federal level surrounding immigrant eligibility for SSI and Medicaid. The federal budget agreement

(April 1997) would restore SSI to those immigrants who become disabled after entering the United States; eliminate restrictions on SSI and Medicaid for qualified immigrant children; delay the ban on food stamps for current recipients from April 1, 1997 to September 30, 1997; and extend the exception for refugees and asylees from five to seven years. However, members of Congress continue to debate the extent of the restoration of benefits for immigrants. Most of the discussions have focused on the SSI program. Two particular amendments were passed to the Senate version of the Balanced Budget Act. The first amendment would exempt qualified immigrants who come in the future and are too disabled to naturalize from the SSI restrictions. The second amendment would allow Amerasians to receive SSI and all other benefits during their first seven years in the United States. While the Senate version passed a few amendments revising provisions impacting immigrants, the House version of the Balanced Budget Act did not include any such provisions. The conference committee is currently meeting to iron out the differences between the House and the Senate bills. According to the National Law and Immigration Center, the House and Senate Republican conferees decided to support the provisions least favorable to immigrants in cases where the House and Senate versions of the bill diverge. As of July 23, 1997, the bill would provide SSI to qualified immigrants who were receiving SSI on August 22, 1996; all other classes of immigrants are not qualified and therefore face the termination of their benefits. These decisions are not final, however, until the White House and the Congress complete their negotiations over the balanced budget bill.

Several governors and congressional members feel strongly that the federal government should reassume its responsibility and restore SSI and food stamps benefits for legal immigrants. States are afraid of taking action to replace those benefits with state funds while there is still no resolution at the federal level. It is felt that by assuming this responsibility, states would be weakening their position vis-à-vis the federal government. On the other hand, states face internal pressures to protect immigrants by replacing benefits. Pro-immigrant legislators, social service providers and advocacy groups argue that, although the federal government should ultimately be responsible, with the enactment of PRWORA, "the ball is now on the states' court." There are indications that large sectors of the population view as unacceptable the human, public health and economic costs of denying assistance to poor legal immigrants. For example, in California, a recent survey of registered voters showed that 92 percent support public benefits for legal immigrants[1].

There is consensus that the immigrant provisions of the Welfare Act represent an unprecedented cost transfer from the federal government to the states. Besides the direct costs of providing benefits, there would be significant administrative costs if states were to establish their own programs to serve immigrants. For example, if a state wanted to replace food stamps it would need to create a new program for immigrants, while citizens will continue to be served by the U.S. Department of Agriculture (USDA) food stamps program. Another possibility would be for the states to contract out the provision of benefits for immigrants with the federal government. Currently, a federal bill (HR1469), which has not been passed yet,

[1] The survey, conducted by the Service Employee International Union, polled a sample of registered voters who have voted in recent elections about various topics--the questions on public benefits for legal immigrants constituted a small section of the questionnaire. The results of this survey will be available soon.

contains language permitting states to contract with USDA to continue providing food stamps to legal immigrants.

In addition to the cost-shifting issue, states question whether the federal government has the right to force states to make decisions about public benefits for immigrants. States argue that "immigration policy", i.e. determining and enforcing the conditions under which non-citizens can enter and reside in the country legally, is a federal responsibility. Therefore, states should not be faced with the responsibility of having an "immigrant policy", i.e. determining whether immigrants, whom they did not admit, may receive benefits. Nor should states be asked "to act as agents of the INS". An individual interviewed for this study illustrated this paradox by suggesting that if the federal government wants to decentralize immigrant policy, it should also be willing to decentralize immigration policy.

Policy options regarding federal programs

The decisions that states need to make regarding federal programs can be classified in three types:

1) Immigrant eligibility decisions, i.e. whether immigrants should be covered and which types of immigrants should be covered.

2) Economic decisions, i.e. determining the level of benefits to be offered to immigrants.

3) Administrative decisions, i.e. whether to create new state programs or reform current programs to serve immigrants.

SSI

According to the welfare act, with the exception of five immigrant categories, all non-citizens will lose eligibility for SSI. However, as discussed above, there is still great uncertainty around the continuation of the SSI program for immigrants. States will have to decide whether to establish a state-funded program to replace benefits for those immigrants who will eventually lose SSI. The range of decisions that states need to make are summarized in Table 4.1.

Table 4.1: Range of State Decisions Regarding Replacement of SSI for Immigrants

Immigrant eligibility decisions
Whether to wait until the federal budget is passed and it is clear which types of immigrants will lose SSI.
Whether to create a state program to replace SSI. If this program is created before the federal budget is passed, the state will have to estimate which types of immigrants are less likely to be covered by the federal government.
Whether to cover only qualified aliens as defined in the Welfare Act or all legal aliens (qualified and non-qualified).
Whether to cover only qualified (legal) immigrants who entered the country before the

enactment of PRWORA (current immigrants) or cover all qualified (legal) immigrants regardless of their date of entry.
Whether to subject state-funded coverage for qualified (legal) immigrants who entered the country after the enactment of PRWORA (new immigrants) to deeming.
Economic decisions
Level of benefits.
Administrative decisions
Structure of state program to replace SSI.
If there are state programs linked to SSI (e.g. in-home support services, Medicaid), state may want to de-link eligibility to allow immigrants losing SSI to continue receiving benefits/services under those programs.

Food stamps

According to the Welfare Act, with the exception of five immigrant categories, all non-citizens will lose eligibility for food stamps. States will have to decide whether to establish a state-funded program to replace food stamps. The range of decisions that states need to make are summarized in Table 4.2.

Table 4.2: Range of State Decisions Regarding Replacement of Food Stamps for Immigrants

Immigrant eligibility decisions
Whether to discontinue food stamps for immigrants by April 1, 1997 or promote recertification of immigrants to receive food stamps to delay discontinuation.
Whether to create a state program to replace food stamps.
Whether to cover only qualified aliens as defined in the Welfare Act or all legal aliens (qualified and non-qualified).
Whether to cover only qualified (legal) immigrants who entered the country before the enactment of PRWORA (current immigrants) or cover all qualified (legal) immigrants regardless of their date of entry.
Whether to subject state-funded coverage for qualified (legal) immigrants who entered the country after the enactment of PRWORA to deeming.
Economic decisions
Level of benefits.
Administrative decisions
Whether to extend recertification periods as far as possible, but in any event not later than August 22, 1997. This option is from the waiver the USDA Food and Consumer Service issued subsequent to the enactment of PRWORA. The waiver allows States to extend certification periods for aliens currently receiving Food Stamps for up to 12 months, or up

to 24 months in the case of elderly and disabled aliens, but not past August 22, 1997.
Whether to seek a waiver from USDA to exempt able-bodied, childless adults between the ages of 18 and 50 from the Federal welfare provisions if those individuals live in a county with an unemployment rate greater than 10 percent. Also, counties could qualify for a different waiver because of their designation as "labor surplus areas."
If HR1469 is passed, whether to contract with USDA to continue providing food stamps to immigrants who lose assistance or create state program to replace food stamps.
Structure of state program to replace food stamps.

TANF

According to the Welfare Act states are authorized to determine the eligibility of qualified aliens for TANF. Federal funds may be used for covering qualified immigrants. States may use their own funds to cover non-qualified and new immigrants. The range of decisions that states need to make are summarized in Table 4.3.

Table 4.3: Range of State Decisions Regarding Continuation & Replacement of TANF for Immigrants

Immigrant eligibility decisions
Whether to continue covering qualified immigrants. Federal funds may be used for covering qualified immigrants. If the state decides to cover qualified immigrants, the block grant amount received from the federal government, in combination with the corresponding state funds, should be sufficient to cover those immigrants. The state may decide to cover only certain types of qualified immigrants.
Whether to use state funds to cover all legal immigrants (i.e. qualified and non-qualified immigrants). Federal funds may not be used to cover non-qualified immigrants.
Whether to cover only qualified (legal) immigrants who entered the country before the enactment of PRWORA (current immigrants) or cover all qualified (legal) immigrants regardless of their date of entry. During the five year ban, federal funds may not be used to cover new qualified immigrants. After the five-year ban, federal funds may be used to cover qualified immigrants but states must deem the income and resources of the alien's sponsor.
Whether to subject state-funded coverage for qualified (legal) immigrants who entered the country after the enactment of PRWORA to deeming.
Whether to cover citizen children of non-qualified immigrants.
Economic decisions
Level of benefits.
Administrative decisions
TANF implementation decisions around immigrants including:
Whether the state will implement any immigrant-specific programs in regard to work

requirements, e.g. job training programs in appropriate languages Whether the state plans to include any immigrant categories (e.g. refugees) in the fraction of recipients to be exempted from the TANF work requirements If the state decides to cover new qualified or non-qualified immigrants, whether the state will have this spending count towards the "maintenance of effort" requirement for TANF under PRWORA TANF implementation decisions around households composed of non-citizen and citizen members including: Whether new qualified, non-qualified and illegal immigrant parents of citizen children will be eligible for limited assistance Whether new qualified and non-qualified immigrant parents will have to meet work requirements Whether undocumented immigrant parents will be required to meet work requirements through community service, since they are not legally permitted to work in the United States Whether single undocumented immigrant parents will be eligible for child care.

Medicaid

According to the Welfare Act states are authorized to determine the eligibility of qualified aliens for Medicaid. Federal funds may be used for covering qualified immigrants. States may use their own funds to cover non-qualified and new immigrants. Emergency Medicaid must be available to all types of immigrants--including illegal immigrants. The range of decisions that states need to make are summarized in Table 4.4.

Table 4.4: Range of State Decisions Regarding Continuation & Replacement of Medicaid for Immigrants

Immigrant eligibility decisions
Whether to continue covering qualified immigrants. Federal funds may be used for covering qualified immigrants. The state may decide to cover only certain types of qualified immigrants. Whether to use state funds to cover all legal immigrants (i.e. qualified and non-qualified immigrants). Federal funds may not be used to cover non-qualified immigrants. Whether to cover only qualified (legal) immigrants who entered the country before the enactment of PRWORA (current immigrants) or cover all qualified (legal) immigrants regardless of their date of entry. During the five year ban, federal funds may not be used to cover new qualified immigrants. Whether to cover citizen children of nonqualified immigrants and whether to distinguish between children in a family with citizen and nonqualified immigrants children. Whether to subject coverage for qualified (legal) immigrants who entered the country

after the enactment of PRWORA to deeming.
Economic decisions
Level of benefits
Administrative decisions
Whether to establish eligibility criteria (i.e. medically needy) to allow immigrants who lose SSI to continue receiving Medicaid--such criteria may already exist.

Policy options regarding state and county programs

Besides restricting immigrant eligibility for federal programs, the Welfare Act limited immigrant eligibility for state and county programs. States are authorized to determine the eligibility of qualified immigrants who entered the United States before August 22, 1996, for state and county programs. States are also authorized to determine the eligibility of non-immigrants under the Immigration and Nationality Act and aliens paroled into the United States for less than a year. If a state wants state and county programs to cover non-qualified and illegal immigrants, it has to enact a state law after the enactment of PRWORA that affirmatively provides for such eligibility.

State legislative and policy decisions regarding immigrant-related provisions of Welfare Act

As described above, states are faced with making multiple decisions regarding the immigrant-related provisions of the Welfare Act. Among the five states we surveyed, there is considerable variation in the extent to which decisions have been made. The legislative sessions in Florida, Illinois and Texas have ended. On the other hand, in California and New York, the legislatures are in session and there are still many uncertainties. In this section, we present an overview of the legislative and policy decisions that these five states have made through this point in time. This, of course, does not mean that the states in question will not continue debating how to respond to the immigrant provisions of PRWORA. When the federal budget is approved, states may have to both reconsider their positions and evaluate issues they have not addressed yet. Additionally, once PRWORA is fully implemented, states will have to confront its impacts on immigrants.

Among the five states in this study, there is a wide range of responses to the immigrant provisions of the Welfare Act. Texas appears to be at one end of the spectrum. Several interviewees stressed that the state seems to be "in denial" of the devastating effects that PRWORA will have on the immigrant population. On the other hand, Illinois has already made two important decisions, i.e. replacing SSI for a fraction of those immigrants who may lose benefits and continuing prenatal care for all types of immigrants. Furthermore, Illinois appears to be the only state where practically all the range of policy options discussed in Section 2, have been considered. California, Florida and New York are between Texas and Illinois with regard to reaching consensus on a policy framework to determine program changes at the state and local levels of government. A complete discussion of each state is included in the case studies in this report.

Some of the issues that states have not fully addressed yet are whether to use state funds to cover non-qualified legal immigrants, i.e. persons residing in the United States under color of law (PRUCOL immigrants); whether to use state funds to cover immigrants who entered the United States after August 22, 1996 (new immigrants); and whether to subject coverage of new immigrants with state funds to the new deeming provisions.

State legislative and policy decisions regarding federal programs

Below we discuss the decisions that states have made regarding food stamps, SSI, TANF and Medicaid. Tables referenced follow on pages 19 through 22.

SSI

Except for Illinois, none of the states has decided to allocate state funds to replace SSI for those immigrants who will lose benefits. The Illinois legislature has appropriated $10 million to cover 4,192 elderly legal immigrants who applied for SSI before August 22, 1996. At the federal level, the governors and/or congressional members of California, Florida, Illinois and New York have advocated that the federal government restore SSI. To our knowledge, Texas is the only state that has not been openly active at the federal level.

Food stamps

None of the states has made a decision to create a program to replace the food stamp program for immigrants. In California and New York, the creation of such program is being considered. For the time being, Illinois and Florida have decided against this option. Finally, the issue of replacing food stamps with a state-funded program has not been raised in Texas. In general, although the consequences of not restoring or replacing food stamps will be as devastating as the consequences of not restoring or replacing SSI, at the state level there is considerably less political support for food stamps than for SSI. At the federal level, the governor and/or congressional members of California, Florida, Illinois and New York have advocated that the federal government restore food stamps. However, discussions at the federal level have focused on SSI, and advocacy for food stamps has been less vocal. Again, to our knowledge, Texas is the only state that has not been strongly lobbying at the federal level.

Although the replacement of food stamps for legal immigrant has not received as much attention as the replacement of SSI benefits, numerous advocacy groups are deeply concerned about the consequences of denying food stamps to non-citizens.

As illustrated later in this report (see Tables 6.1 and 6.2), in terms of the number of individuals losing benefits, the denial of food stamps will be even more serious than the denial of SSI. In terms of lost federal funds, the loss of SSI would be roughly 150 percent larger than the loss of food stamps for Florida, 130 percent larger for Illinois, and 7 percent larger for Texas -- data for California and New York were not available. However, the amount of federal funds lost for both programs is significant. Additionally, the figures in Tables 6.1 and 6.2 do not

reflect that Congress is likely to restore SSI benefits for at least a fraction of immigrants, while restoring food stamps is not being considered[2].

Besides the direct impact on state finances, food stamp cuts will have a severe effect on legal immigrants' income. For instance, according to California Food Policy Advocates, in the state of California the average immigrant household cut from the program will lose about $70 per person monthly. For immigrant families in Los Angeles and San Francisco, this will represent a reduction in their monthly income of one-fourth and one-third respectively.

Food stamp cuts will result in increased malnutrition. In California, several advocacy groups have stressed that the denial of food stamp benefits to legal immigrants will cause the largest increase in food insecurity since the Great Depression. Food stamp cuts will have serious consequences for both immigrant and citizen children. For instance, in California children represent about one-third of those legal immigrants who are likely to lose food stamps. Furthermore, citizen children whose non-citizen parents and/or siblings will lose food stamps will be negatively impacted by a reduction in their family's ability to purchase food. In turn, increased malnutrition and hunger will give rise to health problems (e.g. anemia, low-birth weight and growth stunting) as well as educational problems.

Finally, the discontinuation of food stamp benefits will have a large negative impact on local economies. In addition to the direct loss of purchasing power, studies have shown that there is a three-fold multiplier effect associated with food stamps[3]. Some local economic interests realize the negative effect that the food stamp cuts may have on them and a few have taken some action to address this issue, e.g. in Houston some grocery stores have begun disseminating information on naturalization because of concerns about potential losses in food stamp revenue. However, none of the individuals interviewed for this study mentioned any efforts on the part of local chambers of commerce or other economic interests to lobby state governments and/or legislatures to replace food stamps. An additional economic impact of the loss of food stamps will be the removal of an implicit subsidy from the federal government to employers. By providing food stamps, the federal government has helped improve the economic well-being, nutritional status, and productivity of important sectors of the workforce. For instance, off-season, food stamps help immigrant farm workers support themselves and their families. Without food stamps, employers are likely to face a less productive workforce. However, interviewees did not note any employer efforts to advocate for the replacement of food stamps.

As mentioned above, in general, at both the state and federal levels, there appears to be more political support for protecting the elderly and disabled population, while both Congress and the public have been less sympathetic towards families and children who will lose food stamps. However, in the months to come, as the effects of the food stamp cuts are fully understood and realized, it is likely that state governments, legislators and local economic interests will advocate more aggressively for the restoration of these benefits and/or take action to replace

[2] President Clinton did not provide for the restoration of food stamps for legal immigrants in his budget proposal.
[3] The size of the multiplier effect comes from the California Food Policy Advocates, the Texas's, Comptroller and the El Paso Chamber of Commerce. The three sources agree that the food stamp multiplier (i.e. the indirect impact on local economies of losing direct food stamp funds) is about 3.0.

them. The announcement by Governor Pataki on July 23, 1997 that New York is likely to replace food stamps at least for children, the elderly or disabled who have legal immigrant status points in this direction[4].

TANF

All states have decided to preserve TANF eligibility for qualified immigrants who entered the country before the enactment of PRWORA. Florida and Illinois already have decided against covering new qualified immigrants, while California and New York are still considering this option. With respect to non-qualified immigrants, Florida, Illinois and New York have decided against it, while California is still evaluating this alternative. In the last legislative session, the Texas legislature did not contemplate coverage for either new qualified or non-qualified immigrants.

States are now considering how to treat families comprised of immigrant parents (qualified and nonqualified) and citizen children. As the above table highlights, in Florida and Illinois, citizen children of nonqualified immigrants will receive benefits and their cases will be referred to as child only cases. These two states are not going to require the nonqualified immigrants to meet any work or community service requirements. The State of Illinois is planning on exempting these children from the five-year time-limit ban; it is not clear whether Florida will also exempt these children from the time limit. Similar to Florida and Illinois, the state of California will provide benefits to citizen children of nonqualified and qualified immigrants. However, in contrast to Florida and Illinois, California will not exempt these nonqualified immigrant parents from the work requirement; rather, these immigrants will be required to participate in community service activities. At this point in time, it is unclear how Texas and New York will treat the citizen children. No additional documentation or information was available.

Table 4.5 Overview of the Immigrant Provisions of the State TANF Plans

	California	Florida	Illinois	New York	Texas
TANF effective date	10/9/96	10/1/96	5/1/97	12/2/96	10/1/96
Time limit	60 mos.	48 mos.	60 mos.	60 mos.	12 continuous mos., 60 mos. lifetime
Provide TANF to qualified immigrants	Yes	Yes	Yes	Yes	Yes
Provide TANF to nonqualified immigrants:					
Who entered the U.S. prior to 8/22/96	No	No	No	No	No
Who entered the U.S. after 8/22/96	No	No	No	No	No
Provide TANF to citizen children of nonqualified immigrant parents	Yes	Yes	Yes	Info N/A	Info N/A
Establish work requirements for nonqualified parents whose citizen children are receiving benefits	Yes, community service	No	No	Info N/A	Info N/A

Exempting certain qualified immigrants from work requirements	To be decided	No	To be decided	Info N/A	Info N/A
Subjecting new immigrant eligibility and coverage to deeming	Yes	Yes	Yes	Yes	Yes

Source: State TANF Plans

Under the TANF, states have the option of exempting a segment of the population from the work requirements. At this point in time, it appears that only one state (California) is considering whether to exempt refugees, asylees, or parolees. The remaining states will require qualified immigrants to meet the work requirements. In addition, the states have also stated that they plan on subjecting immigrant eligibility and coverage to deeming as stated in PRWORA.

Medicaid

All states have decided to preserve Medicaid eligibility for all qualified immigrants who entered the country before the enactment of PRWORA. Illinois and Florida have decided against covering new qualified immigrants, while California and New York are still considering this option. With respect to non-qualified immigrants, Florida, Illinois and New York have decided against it, while California is still evaluating this possibility. Texas did not contemplate coverage for either new qualified or non-qualified immigrants.

V. STATE DECISIONS AND ACTIONS

Table 5.1: State Policy Decisions Regarding Replacement of SSI Benefits for Immigrants

State	State will replace SSI for pre 8/22/96 qualified immigrants				State will replace SSI for post 8/22/96 qualified immigrants				State will replace SSI for non-qualified immigrants				Governor has openly advocated the federal government restore SSI		Congressional members have sponsored bills to restore SSI	
	Yes	No	TBD	NC	Yes	No	TBD	NC	Yes	No	TBD	NC	Yes	No	Yes	No

Texas				X				X				X		X[5]		X

Note: *Yes* indicates that a bill or budget appropriation to replace food stamps has been passed; *No* indicates that a bill or budget appropriation to restore food stamps did not pass; *TBD* (to be decided) indicates that a decision about a bill or budget appropriation to restore food stamps has not been made yet; *NC* (not considered) indicates that a bill or budget appropriation to restore food stamps has not been considered.

[5] Interviews with the Governor's Office have not been completed; a statement from the Governor's Office is forthcoming.

Table 5.3: State Policy Decisions Regarding TANF Benefits for Immigrants

State	State will cover pre 8/22/96 qualified immigrants (as stated in TANF plan)		State will cover post 8/22/96 qualified immigrants at state's cost				State will cover non-qualified immigrants at state's cost			
	Yes	No	Yes	No	TBD	NC	Yes	No	TBD	NC
California	X				X				X	
Florida	X			X				X		
Illinois	X			X				X		
New York	X				X			X		
Texas	X					X				X

Note: For qualified immigrants, *Yes* indicates this is the state's intent under TANF plan; *No* indicates that this is not state's intent under TANF plan. For new and non-qualified immigrants, *Yes* indicates that a bill or budget appropriation to replace TANF has been passed; *No* indicates that a bill or budget appropriation to restore TANF did not pass; *TBD* (to be decided) indicates that a decision about a bill or budget appropriation to restore TANF has not been made yet; *NC* (not considered) indicates that a bill or budget appropriation to restore TANF has not been considered.

Table 5.4: State Policy Decisions Regarding Medicaid Benefits for Immigrants

State	State will cover pre 8/22/96 qualified immigrants		State will cover post 8/22/96 qualified immigrants at state's cost				State will cover non-qualified immigrants at state's cost			
	Yes	No	Yes	No	TBD	NC	Yes	No	TBD	NC
California	X				X				X	
Florida	X			X				X		
Illinois	X			X				X		
New York	X				X			X		
Texas	X					X				X

Note: For qualified immigrants, *Yes* indicates that state intends to cover these immigrants; *No* indicates that state does not intend to cover these immigrants. For new and non-qualified immigrants, *Yes* indicates that a bill or budget appropriation to replace Medicaid has been passed; *No* indicates that a bill or budget appropriation to restore Medicaid did not pass; *TBD* (to be decided) indicates that a decision about a bill or budget appropriation to restore Medicaid has not been made yet; *NC* (not considered) indicates that a bill or budget appropriation to restore Medicaid has not been considered.

VI. ACTUAL & EXPECTED IMPACTS OF THE WELFARE ACT ON IMMIGRANTS

Estimates of the number of immigrants losing benefits by federal program

Table 6.1 shows estimates of the number of immigrants who are likely to lose benefits. The number of immigrants who will lose SSI will be subject to the final outcome of the federal budget negotiations. For TANF and Medicaid, the five states have opted to cover qualified immigrant who entered the United States before the enactment of PRWORA. Illinois and Florida were able to provide estimates of the number of PRUCOL individuals who will lose TANF and Medicaid because they are no longer eligible under the welfare act. However, the other states did not provide these data.

It is important to note that the estimates provided by the states reflect only the number of *current recipients* who are likely to lose benefits. Furthermore, under PRWORA, except for the exempted categories, legal immigrants who entered the country before August 22, 1996 will not be able to apply for food stamps and SSI. New legal immigrants will not be able to apply for food stamps, SSI, TANF and Medicaid. Therefore, the estimates in Table 6.1 are a conservative estimate of the impact of the Welfare Act on immigrants. Ideally, estimates of the number of immigrants who would apply for benefits if they were still eligible should be added to the number of current recipients losing benefits.

The data in Table 6.1 show that in terms of the number of current recipients losing benefits, the largest impact would be felt by food stamp and SSI recipients. About 750,000 immigrants will lose food stamps in the five states, while about 430,000 immigrants will lose SSI.

Table 6.1: Number of Current Recipients by States to Become Ineligible by Program

	Food Stamps	SSI	TANF	Medicaid
California	345,000	243,720	N/A	N/A
Florida	97,658	54,000	503[a]	3,062 [a b]
Illinois	39,000	22,000	1,698[a]	2,379[a]
New York	130,000	80,000	N/A	N/A
Texas	140,937	34,892	N/A	37,061 (State option); 33,725 (SSI-linked)

California: Data provided by the California Department of Social Services. SSI data do not take into account the provisions of the federal budget agreement.
Florida: AFDC, Food Stamp, and Medicaid data as of January 1997; SSI data as of December 1996. Data provided by the State Department of Children and Families Economic Self-Sufficiency Services Program,
Illinois: Data provided by the Illinois Department of Public Aid. SSI data do not take into account the provisions of the federal budget agreement.
New York: Food stamps data come from USDA; SSI data provided by the State Department of Social Services,
Texas: Data from the Texas Health and Human Services Commission, Report of the Interagency Workgroup on Welfare Reform, November 1, 1996. The 37,061 Medicaid estimate is based on July 1996 caseloads and indicates the minimum number of legal aliens who will be subject to the State's option to continue coverage. The 33,725 Medicaid estimate is based on updated SSI caseloads from January 1997. The figure indicates the number of aged and disabled qualified aliens receiving SSI who were not receiving institutional care and would be likely to lose Medicaid even if the state opted to continue coverage, because their only access to Medicaid was through SSI.
a:/Permanently Residing Under Color Of Law
b:/Not including SSI recipients

Estimates of the costs to the states by federal program

As illustrated in Table 6.2 for those states that provided estimates, the loss of federal funds due to the immigrant provisions of PRWORA will be considerable. For food stamps and SSI, Florida will lose nearly $311 million per year, while Illinois and Texas will lose about $150 million each. As explained above, these figures may change once the federal budget is approved. Under the Welfare Act, the most significant financial loss to the states will be the loss of SSI funds.

Table 6.2: Estimated Costs of Federal Welfare Reform to the States

	Food Stamps	SSI	TANF	Medicaid
California	N/A	N/A	N/A	$16,000 [a]
Florida	$89,064	$221,616	$561	$3,123
Illinois	$46,000	$105,000	N/A	$12,300 [b]
New York	N/A	N/A	N/A	N/A
Texas	$122,200	$130,300	$9,000	$90,000 (State option); $94,600 (SSI-linked)

Notes: Numbers in thousands of dollars. Unless otherwise indicated, figures reflect amount of lost federal funds for current recipients (per year).
California: Data provided by the Legislative Analyst's Office. a:\ Yearly cost to the state of covering new immigrants.
Florida: AFDC, Food Stamp, and Medicaid data as of January 1997; SSI data as of December 1996. Data provided by the State Department of Children and Families Economic Self-Sufficiency Services Program.
Illinois: Data provided by the Illinois Department of Public Aid (IDPA). SSI data do not take into account the provisions of the federal budget agreement. b:\ Yearly cost to the state of covering PRUCOL recipients (estimated by IDPA).
Texas: TANF estimates from Legislative Budget Board, December 1996. SSI, Food Stamps, and Medicaid estimates from the Texas Health and Human Services Commission, Report of the Interagency Workgroup on Welfare Reform, November 1, 1996. The $90 million loss for SSI indicates the dollar value of coverage for legal aliens subject to the State's option to continue coverage. The $94.6 million indicates the dollar value of coverage for aged and disabled qualified aliens receiving SSI who were not receiving institutional care and would be likely to lose Medicaid even if the state opted to continue coverage, because their only access to Medicaid was through SSI.

Impacts on immigrants

Although PRWORA has not been fully implemented, state and county officials, social service providers and pro-immigrant advocacy groups in the five states in this study provided both data and compelling anecdotal evidence suggesting that the Act will have a significant negative impact on the well-being and health of large sectors of the immigrant population. The effects of PRWORA are discussed below.

Fear and confusion among the immigrant population

The Welfare Act has created widespread fear and confusion among immigrants. As discussed earlier, the final form that the immigrant provisions of PRWORA will take has yet to be determined. Even state and county officials, and advocates specialized in welfare and immigration issues find it difficult to fully understand the language and implications of the Act, and to keep track of its evolution. For low-income immigrants, many of whom are elderly, disabled, or not fully proficient in English, the technicalities of PRWORA may be incomprehensible. However, they are aware of the "bottom line", i.e. they will lose their benefits because they are immigrants.

Effects on the socio-economic status of immigrants

By limiting eligibility to various public assistance programs, the Welfare Act will significantly reduce the income of those immigrant families who are currently receiving benefits. The SSI cuts will affect elderly and disabled legal immigrants, while the food stamp cuts will affect young adults and children. As discussed earlier, among legal immigrants, a substantial fraction of current food stamp recipients are children--e.g. in California roughly one-third of immigrants on the food stamp program are children. Furthermore, the Act will make new legal immigrants ineligible for TANF for five years after they enter the country.

PRWORA will not only have a negative effect on non-citizens but it will increase income, housing and food insecurity among U.S. citizens. In mixed households, i.e households composed of both non-citizens and citizens, a reduction in household income due to the immigrant-related provisions of the Act will impact all the members of the household not only the non-citizen ones.

Effects on the Health Status of Immigrants

By reducing the income of immigrant families by limiting SSI, food stamp and TANF eligibility, PWRORA will put immigrants at risk of malnutrition and inferior housing conditions including overcrowding. In turn, these risk factors will increase the likelihood of health problems among immigrants.

The Welfare Act has also reduced immigrants' access to social and health services. First, according to the Act, non-qualified, new qualified and undocumented immigrants will only be eligible for a narrow range of health services. Furthermore, the difficulty in understanding the scope of PRWORA may result in reduced access to services for which immigrants are still eligible. For instance, in several states nursing homes are already turning away immigrants. Illinois and New York have issued clarification letters to long-term care providers to prevent them from denying admission to immigrants. Additionally, the overlap between the Welfare Act and the Immigration Act has the potential of creating disincentives to access health care and other services. For example, service providers reported that immigrants fear that by using health services they may be at risk of deportation and/or jeopardizing their chances of becoming U.S. citizens.

For illegal aliens, one of the main impacts of PRWORA may be the lack of access to prenatal care. Several interviewees noted that the lack of prenatal care will result in higher health care costs, since high-risk pregnancies among undocumented women will go undetected until the women present themselves at emergency rooms to deliver their babies--according to PRWORA, all types of immigrants are still eligible for emergency health care. Furthermore, children born to these women are U.S. citizens and are eligible for Medicaid. The medical costs incurred in serving children whose mothers did not receive prenatal care have been shown to be higher than for those children whose mothers did receive care. Advocates and public health officials in the five states covered in this report noted that national data have demonstrated that for every dollar spent on prenatal care, three dollars are saved in future health care costs.

Despite overwhelming evidence that both from a public health and a financial perspective, prenatal care is highly effective, California and New York plan to discontinue these services for undocumented immigrants. Although the measure has not been implemented yet, providers already report a decline in prenatal care utilization by illegal immigrants. In California, a legal suit against the state government has delayed the implementation of this measure --originally scheduled for July 1st 1997-- at least until September 1st, 1997. In contrast to California and New York, Illinois has decided to preserve prenatal care for illegal immigrants.

Furthermore, PRWORA may give rise to serious public health problems. For instance, according to the Act, both legal and illegal immigrants can receive treatment if they have symptoms of a contagious disease. However, immigrants, especially illegal ones, are afraid of seeking health care. In Texas, some providers noted that language of PRWORA has the potential of increasing the spread of infectious diseases. For instance, individuals with active tuberculosis whose symptoms are mild may be denied treatment. This is a major concern along the Mexico-Texas border where TB prevalence is very high.

Finally, the Welfare Act is already having a severe negative impact on the mental health status of immigrants. Among individuals receiving SSI, the threat of being left without any means to support themselves has resulted in an increased incidence of mental health problems and suicides. Individuals interviewed for this report cited suicide cases as a dramatic illustration of the "unfairness" of the Welfare Act.

Effects on naturalization and assimilation

As explained in the introduction, there is an intersection between PRWORA and the Immigration Act. Immigrants are responding to both pieces of legislation and may find it hard to distinguish between the welfare and the immigration provisions. Both the threat of not being able to access public benefits and the threat of being deported are inducing a large number of immigrants to apply for citizenship. States, counties and community-based organizations are providing assistance to immigrants who want to seek naturalization. The Welfare Act has changed the incentives to become U.S. citizens facing immigrants. It remains to be seen whether these new incentives and the corresponding expected increase in naturalization rates will result in a faster assimilation process.

Furthermore, the deeming provisions of the Welfare Act--including the enforcement of affidavits of support--may change family reunification strategies among immigrants, e.g. by discouraging bringing into the United States elderly family members and/or small children who are more likely to need economic support.

Increased awareness about and mobilization around immigrant issues

Finally, despite all its negative impacts on immigrants, PRWORA may have at least one unintended positive outcome, that pro-immigrant service providers, community-based organizations and advocacy groups are becoming increasingly organized. For example, in California a bipartisan Committee in the legislature charged with summarizing the state options to respond to PRWORA has incorporated in its report the key initiatives of pro-immigrant groups

and legislators. In Illinois, advocacy groups have defined the terms of the debate. In Texas community-based organizations have been instrumental in explaining the implications of the Welfare Act to the state administration and legislature. Given that states are likely to become increasingly responsible for providing benefits and services to immigrants, pro-immigrant groups will have to strengthen their ability to shape the state political and policy responses towards immigrants.

VII.STATE EFFORTS TO MONITOR IMPACTS

At the present time, none of the states interviewed has an official, comprehensive plan to monitor the impacts of welfare reform change on immigrants. In fact, no state has a comprehensive plan to monitor the effects of welfare reform on other segments of the populations affected by this monumental legislation. The few monitoring studies that do exist focusing on the effects of welfare reform are being conducted by private research institutes funded by private philanthropies. Private organizations in New York and Texas have funded a monitoring project with particular focus on the disabled populations. Two states, New York and Florida, are planning to fund monitoring activities, but neither state has had the staff or other resources at their disposal to develop a monitoring approach.

Florida has a number of locally funded efforts to educate immigrant communities about changes in welfare programs. However, these programs do not link to any state efforts to monitor changes in program management or benefit use. In Texas, a number of charities and local governments are tracking changes in food sales as proxy measure of changes in food stamp circulation. There is no state-initiated effort to study the impact of changes in the food stamp program on the local economy or the nutritional status of populations at-risk.

The most immediate, albeit crude, tool available in each state to monitor changes in welfare programs is the monthly or quarterly caseload. These caseload figures are collected by each of the programs. In California and Texas, information on joint state/county-funded and county-only-funded welfare programs have been maintained primarily at the county level. In New York, the responsibility for maintaining information systems for welfare administration is devolving to the counties. Florida and Illinois have maintained centralized information systems for the state-funded welfare programs. However, in Florida county-only welfare programs are maintained by the counties and municipalities.

Clearly, states and counties are faced with several decisions regarding developing the capacity to track welfare program beneficiaries and resource use across localities. With changes in the lifetime limits imposed by the federal legislation and changes in eligibility requirements for immigrants, even the limited information systems currently maintained by states and counties will be inadequate to assure compliance with federal law. At present, of the states included in this study, none has indicated a current effort to integrate county and state information systems to track welfare caseload and benefit use across welfare programs and for specific classes of recipients, including immigrants.

States will have to rely increasingly on systems that track information on immigrants. The single federally-developed information system currently available to states that can provide information

on immigrant status is known as the Systematic Alien Verification for Entitlements (SAVE) Program. This is an intergovernmental information-sharing service for agencies and institutions that was developed pursuant to Section 121 of the Immigration Reform and Control Act of 1986 (IRCA).

Program components include a database of selected immigration status information on approximately 50 million individual non-citizens. The database is updated daily by the INS. States are using this information system to determine primary immigration status. However, states must still develop information systems that track immigrant categories and exemption criteria as defined in the Welfare Act. States are currently waiting for the U.S. Attorney General to develop verification criteria and procedures, and then they will have a year to make their systems conform to the new guidelines.

California, New York, Florida, and Texas are not developing centralized administrative information systems that link immigrants receiving state or local welfare benefits to immigration verification systems. Each county and municipality will be responsible for developing that capability. None of these states has plans to develop the capacity to electronically summarize the information linking immigrants to welfare programs or other tracking systems. Illinois has a centralized system, but immigrant categories are not uniform across programs. The prospects for developing centralized capabilities to monitor changes of welfare reform on immigrants are not bright. State and local resource constraints, competing demands for investments in information systems, and continuing devolution of responsibilities for program administration and financing to local government work against the likelihood that states will put a high priority on building a centralized capability to track the impact of welfare reform for immigrants and other populations affected by this historic change in welfare programs in the United States.

There remain public health interests in monitoring the impact of welfare reform at the state and local levels despite the apparent disinterest or disinclination of governments to fund these activities. The need to track communicable disease and contacts of individuals with communicable disease transcends local and state boundaries. Public health officials and providers may lose the ability to effectively intervene in the management of infectious diseases, many of which show a higher incidence among the poor and among immigrants from selected countries. Despite the limitations of current state and local tracking systems, it is possible to develop simulation techniques to estimate the incidence of disease and the patterns of infection for small areas and large regions to assist in the control of communicable disease among the population at-large. There is an immediate national interest in mitigating the worst effects that restrictions on access to public benefits and medical care may have on at-risk populations among immigrants.

VIII. CONCLUSIONS

The five states in this study are only starting to respond to the immigrant provisions of the Welfare Act. However, the current status of decisionmaking should not be viewed as inaction by the states. With the exception of Texas, all states are assessing various policy options ranging from covering all immigrants to minimizing state responsibility in this area. States are faced with both a significant cost shift from the federal government and the need to make complex decisions about immigrant eligibility. This transfer of immigrant-related costs and policy decisions is

unprecedented and states are challenging the constitutionality of many of the provisions in the Welfare Act, if not the Act in its entirety. Additionally, since states are unlikely to have the ability to completely replace federal benefits, immigrants will have access to lower levels of assistance.

In addition to the transfer of "immigrant policy" to the states, PRWORA raises another important question, i.e. whether it is legitimate to use welfare benefits as an immigration policy tool. First, the Welfare Act assumes that the availability of public benefits constitutes an incentive for immigration to the United States[6]. However, it is questionable whether immigrants factor public benefits into their decision to migrate[7]. Second, PRWORA seeks to reduce public assistance in order to generate incentives for individuals to work. However, for immigrants PRWORA also creates an incentive to naturalize in order to remain eligible for benefits.

Furthermore, a recent report by the National Academy of Sciences has shown that, overall, immigrants make a positive contribution to the U.S. economy. Furthermore, although at the state and local level immigrants have a negative fiscal impact, at the federal level they have a larger positive impact, resulting in an overall positive impact. Therefore, from a fiscal standpoint it should be questioned whether it is acceptable to use immigration status as an eligibility criteria for public benefits.

The effects of the immigrant related provisions of the Welfare Act will be far reaching. State and local governments will face new responsibilities, increased fiscal pressures and complicated administrative decisions. Local economies will be seriously affected by the direct loss of benefits as well as the indirect economic impact associated with diminished household incomes, purchasing power and workforce productivity. Community-based social service and health care providers are likely to face an increased demand for their services as immigrants are denied public benefits. Whether the financial and structural capacity of these providers will be sufficient to offer a safety net to immigrants remains to be seen[8]. Immigrant families will be the most negatively impacted by PWRORA. The effects on immigrants include fear and confusion, diminished household incomes, increased food and housing insecurity, reduced access to health care and other social services, and changing incentives regarding naturalization, assimilation and family reunification strategies. The weakening of immigrants' socio-economic status and well-being will have a detrimental effect not only on immigrants themselves but on those U.S. citizens who are members of immigrant families and households as well as on communities where immigrants constitute a substantial fraction of the population, work force and social fabric.

[6] See PRWORA, Section 400: "Statements of National Policy Concerning Welfare and Immigration".

[7] In the literature, migration flows have been explained as a function of wage and unemployment rate differentials between the origin and the destination country, and as a function of immigrant networks. See Madeline Zavoday. "Welfare and the Locational Choices of Immigrants," Federal Reserve Bank of Dallas Economic Review.. Second Quarter, 1997.

[8] A recent study of the impact of welfare reform in Los Angeles has shown that the capacity of the non-profit sector will be insufficient to fill the subsistence and human service gaps created by welfare reform (Wolch and Sommer, 1997, *Los Angeles in an Era of Welfare Reform*).

Appendix I Title IV Personal Responsibility and Work Opportunity Act of 1996

Appendix II Summary of Restrictions on Eligibility to Public Welfare Benefits

Appendix III List of Key Interviewees and Sources

Appendix IV Interview Protocol

Appendix V Outline for State Reports

Appendix I. Title IV Personal Responsibility and Work Opportunity Reconciliation Act of 1996

Appendix II. Summary of Restrictions on Eligibility to Public Welfare Benefits

Personal Responsibility and Work Opportunity Reconciliation Act (PRWORA) of 1996
Limitations on immigrants' eligibility for federal, state and local public benefit programs

Federal programs	**Current immigrants** (i.e. aliens entering the country before the enactment of the Act)	**New immigrants** (i.e. aliens entering the country after the enactment of the Act)
"Specified Federal programs"- SSI	**Legal-qualified:** Not eligible Exceptions: refugees; asylees; aliens whose deportation has been withheld; permanent residents (i.e.,. green card holders) who have worked for 40 qualifying quarters and did not receive any means-tested federal public benefits; veterans; aliens on active duty **Legal-non qualified:** (Not Eligible) **Illegal:** (Not Eligible)	**Legal-qualified: (**Not Eligible) **Legal-non qualified:** (Not Eligible) **Illegal:** (Not Eligible)
"Specified Federal programs" - Food stamps	**Legal-qualified (i.e. permanent residents, asylees, refugees, aliens paroled into the U.S. for at least one year, aliens whose deportation is being withheld):** Not Eligible Exceptions: refugees; asylees; aliens whose deportation has been withheld; permanent residents (i.e., green card holders) who have worked for 40 qualifying quarters and did not receive any means-tested federal public benefits; veterans; aliens on active duty **Legal-non qualified:** (Not Eligible) **Illegal:** (Not Eligible)	**Legal-qualified: (**Not Eligible) **Legal-non qualified:** (Not Eligible) **Illegal:** (Not Eligible)
"Designated federal programs" –	**Legal-qualified:** State is authorized to determine the eligibility of qualified aliens	**Legal-qualified:** Not Eligible for 5 years beginning on the date of entry into the U.S.

TANF(formerly AFDC), Part A of Title IV of the Social Security Act	Exceptions: Until five years after date of entry/grant of asylum/withholding for refugees, asylees and aliens whose deportation has been withheld, permanent residents who have worked 40 qualifying quarters, veterans, aliens on active duty (i.e. the eligibility of these aliens is not at the state's discretion) **Legal-non qualified:** Not Eligible **Illegal:** Not Eligible	After 5-year ban, in determining eligibility states must deem the income and resources of the alien's sponsor Exceptions: refugees; asylees; aliens whose deportation has been withheld; veterans; aliens on active duty; Cuban and Haitian refugees **Legal-non qualified:** Not Eligible **Illegal:** Not Eligible
"Designated federal programs" - Medicaid, a state plan under Title XIX of the Social Security Act	**Legal-qualified:** State is authorized to determine the eligibility of qualified aliens Exceptions: Until five years after date of entry/grant of asylum/withholding for refugees, asylees and aliens whose deportation has been withheld, permanent residents who have worked 40 qualifying quarters, veterans, aliens on active duty (i.e. the eligibility of these aliens is not at state's discretion) **Legal-non qualified**: Not Eligible **Illegal**: Not Eligible	**Legal-qualified:** Not Eligible for 5 years beginning on the date of entry into the U.S. After 5-year ban, in determining eligibility states must deem the income and resources of the alien's sponsor Exceptions: refugees; asylees; aliens whose deportation has been withheld; veterans; aliens on active duty; Cuban and Haitian refugees **Legal-non qualified:** Not Eligible **Illegal:** Not Eligible

"Designated federal programs" - Social services block grant, Title XX of the Social Security Act	**Legal-non qualified:** State is authorized to determine the eligibility of qualified aliens Exceptions: Until five years after date of entry/grant of asylum/withholding for refugees, asylees and aliens whose deportation has been withheld, permanent residents who have worked 40 qualifying quarters, veterans, aliens on active duty (i.e. the eligibility of these aliens is not at state's discretion) **Legal-non qualified:** Not Eligible **Illegal:** Not Eligible	**Legal-qualified:** Not Eligible for 5 years beginning on the date of entry into the U.S. After 5-year ban, in determining eligibility states must deem the income and resources of the alien's sponsor Exceptions: refugees; asylees; aliens whose deportation has been withheld; veterans; aliens on active duty; Cuban and Haitian refugees **Legal-non qualified:** Not Eligible **Illegal:** Not Eligible
"Federal public benefits"	**Legal-qualified:** eligible **Legal-non qualified:** Not Eligible Exceptions: 1. Emergency medical care (Title XIX of the Social Security Act) 2. Short-term, in-kind disaster-relief 3. Public health assistance (not including Title XIX) for immunizations and treatment of symptoms of communicable diseases 4. Programs specified by the Attorney General that provide in-kind assistance at the community level; do not condition the provision of assistance on the recipient's income; are necessary for the protection of life and safety 5. Housing assistance to the extent that the alien was receiving assistance when the Act was enacted **Illegal:** Not Eligible Exceptions: same as above	**Legal-qualified:** Not Eligible for any *federal means-tested public benefit* for 5 years beginning on the date of entry into the U.S. After 5-year ban, in determining eligibility states must deem the income and resources of the alien's sponsor Exceptions: refugees; asylees; aliens whose deportation has been withheld; veterans; aliens on active duty; Cuban and Haitian refugees Exceptions: 1. Emergency medical care (Title XIX, Social Security Act) 2. Short-term, in-kind disaster-relief 3. Assistance under the National School Lunch act 4. Assistance under the Child Nutrition Act of 1966 5. Public health assistance (not including Title XIX) for immunizations and treatment of symptoms of communicable diseases 6. Payments for foster care or adoption assistance (several conditions apply)

"Federal Public Benefits"		7. Programs specified by the Attorney General that provide in-kind assistance at the community level; do not condition the provision of assistance on the recipient's income; are necessary for the protection of life and safety 8. Several programs of student assistance under the Higher Education Act of 1965 9. Means-tested programs under the Elementary and Secondary Education Act of 1965 10. Benefits under the Head Start Act 11. Benefits under the Job Training Partnership Act **Legal-non qualified:** (Not Eligible) Exceptions: Same as above **Illegal:** (Not Eligible) Exceptions: None
State public benefit programs	**Legal-qualified, aliens who are not non-immigrants under the Immigration and Nationality Act, aliens paroled into the U.S. for less than one year:** State authorized to determine eligibility Exceptions: Until five years after date of entry/grant of asylum/withholding for refugees, asylees and aliens whose deportation has been withheld, permanent residents who have worked 40 qualifying quarters and did not receive any federal means-tested public benefit, veterans, aliens on active duty (i.e. the eligibility of these aliens is not at state's discretion) State has the authority to provide for attribution of sponsors income and resources to the alien with respect to state programs ("deeming")	**Legal-qualified:** State authorized to determine eligibility Exceptions: Same as for current qualified immigrants **Legal-non qualified:** (Not Eligible) **Illegal:** (Not Eligible)

State Public Benefit Programs	**Legal-non qualified, non-immigrants:** [State may determine that non-qualified aliens are eligible for state and local public benefits only through the enactment of a state law after the enactment of the Act that affirmatively provides for such eligibility] Exceptions: 1. Emergency medical care 2. Short-term, in-kind disaster-relief 3. Public health assistance (not including Title XIX) for immunizations and treatment of symptoms of communicable diseases 4. Programs specified by the Attorney General that provide in-kind assistance at the community level; do not condition the provision of assistance on the recipient's income; are necessary for the protection of life and safety **Illegal:** State may determine that illegal aliens are eligible for state and local public benefits only through the enactment of a state law after the enactment of the Act that affirmatively provides for such eligibility	
County programs	**Legal-qualified, aliens who are not non-immigrants under the Immigration and Nationality Act, aliens paroled into the U.S. for less than one year:** State authorized to determine eligibility Exceptions: Until five years after date of entry/grant of asylum/withholding for refugees, asylees and aliens whose deportation has been withheld, permanent residents who have worked 40 qualifying quarters and did not receive any federal means-tested public benefit, veterans, aliens on active duty (i.e. the eligibility of these aliens is not at state's discretion)	**Legal-qualified:** State and county authorized to determine eligibility **Legal-non qualified:** (Not Eligible) **Illegal:** (Not Eligible)

County Programs	**Legal-non qualified, non-immigrants:** [State may determine that non-qualified aliens are eligible for state and local public benefits only through the enactment of a state law after the enactment of the Act that affirmatively provides for such eligibility] Exceptions: 1. Emergency medical care 2. Short-term, in-kind disaster-relief 3. Public health assistance (not including Title XIX) for immunizations and treatment of symptoms of communicable diseases 4. Programs specified by the Attorney General that provide in-kind assistance at the community level; do not condition the provision of assistance on the recipient's income; are necessary for the protection of life and safety **Illegal:** State may determine that illegal aliens are eligible for state and local public benefits only through the enactment of a state law after the enactment of the Act that affirmatively provides for such eligibility	

Notes: Information in parenthesis "( )" indicates that although the respective restriction/exemption is not explicitly stated in PRWORA, that appears to be the implication of the Act.

TABLE OF CONTENTS

I. STATE'S (COUNTY'S) RESPONSE TO CHANGES IN FEDERAL, STATE AND COUNTY PUBLIC BENEFITS FOR IMMIGRANTS 2

1. What changes are states planning in response to federal policy changes that discontinue immigrants from specific federal programs and federal/state programs? 2

Federal programs 2
State programs 3

2. How are counties and service providers responding to federal and state welfare reforms? 4

3. How will welfare reform affect the costs to states, counties and providers, particularly with respect to substitution of funds for withdrawn federal payments, and also with respect to other social (i.e. human) costs? 4

Federal programs 4
State and county programs 5

4. What distinctions, if any, are states making to determine eligibility for welfare programs under their reforms with regard to an individual's immigration status, age, disability level or employment status? 5

5. Are there state and local plans to monitor and assess the impact of policy changes? 6

II. IMPACT OF THE WELFARE REFORM ON IMMIGRANTS, STATE AND COUNTY GOVERNMENTS, AND THE COMMUNITY 6

1. What are the direct effects of the policy changes, including health care delivery (access to care, payment for care, cost of care, and quality of care) for immigrants at the community level? 6

2. What are the problems that states, counties and providers report they will face in responding to welfare reform that were previously unforeseen by federal government officials? 6

3. Is the state providing assistance to immigrants to become naturalized or prove qualified status?7

I. State's (county's) response to changes in federal, state and county public benefits for immigrants

1. What changes are states planning in response to federal policy changes that discontinue immigrants from specific federal programs and federal/state programs?

Federal programs

Nutrition programs

How many immigrants will lose food stamps?

Does the state have plans to assist those immigrants who will lose food stamps? If yes, please describe those plans.

What has been the state policy regarding recertification of immigrants to receive food stamps?

Will the state make other federal nutrition programs such as WIC available to non-qualified immigrants?

SSI

How many immigrants will lose SSI? What is the composition of these immigrants (elderly versus disabled)?

Will SSI-linked programs for immigrants (e.g., personal care services) be preserved? How?

TANF/AFDC

How many immigrants were receiving AFDC? What proportion of legal aliens who were receiving AFDC are qualified aliens (as defined by the Act) and therefore may continue receiving benefits? Does the state plan to allow qualified (eligible) immigrant families to receive TANF? What types of qualified immigrants? How many immigrants will lose TANF (AFDC)?

Please provide us with a copy of the TANF plan for the state or with the waiver if there is one in place.

Will TANF be preserved for future legal-qualified immigrants after the 5-year ban?

What will the state do to cover non-qualified (non-eligible) immigrant families who were previously covered under AFDC? Does the state plan to advocate with federal agencies that this spending count toward the state "maintenance of effort" requirement?

Medicaid

How many immigrants were receiving Medicaid? What proportion of legal aliens who were receiving Medicaid are qualified aliens (as defined by the Act) and therefore may continue receiving benefits? Does the state plan to allow qualified immigrants to be eligible for Medicaid? What types of qualified immigrants? How many immigrants will lose Medicaid?

Will Medicaid be preserved for future qualified immigrants after the 5-year ban?

Will the state try to preserve Medicaid eligibility for those immigrants who will lose categorical eligibility (to Medicaid) because they will lose SSI?

Will the state try to preserve Medicaid eligibility for those immigrants who will lose categorical eligibility (to Medicaid) because they will lose TANF?

Title XX

How many immigrants were receiving social services under Title XX of the Social Security Act? What proportion of legal aliens who were receiving Title XX services are qualified aliens (as defined by the Act) and therefore may continue receiving benefits? Does the state plan to allow qualified immigrants to be eligible for Title XX services? What types of qualified immigrants? How many immigrants will lose Title XX services?

Will Title XX services be preserved for future qualified immigrants after the 5-year ban?

Other

How is the state interpreting the provision that non-qualified and illegal immigrants do not have the right to receive “federal public benefits”? How is the state applying the exceptions specified in the Act (e.g., emergency medical care, immunizations, treatment of symptoms of communicable diseases)?

How is the state interpreting the provision that future qualified immigrants cannot receive any federal means-tested public benefits for five years beginning on the date of entry into the United States? How is the state applying the exceptions specified in the Act (e.g., emergency medical care, immunizations, treatment of symptoms of communicable diseases)?

State programs

Will the state limit the eligibility of qualified aliens to state public benefits? What types of qualified legal aliens? What benefits? Please provide a list of those state public benefit programs that are (were) available to qualified immigrants and note those that will no longer be available.

According to the Act, non-qualified aliens are not eligible to receive state public benefits. How is the state interpreting this provision? Does the state plan to challenge it? What kind of state public benefits were non-qualified immigrants receiving? What will happen to these benefits?

Please provide a list of state public benefit programs that are (were) available to non-qualified immigrants and note those that will no longer be available.

According to the Act, illegal aliens are not eligible to receive state public benefits *unless* a state law is enacted after the enactment of the Act that affirmatively provides for such eligibility. How is the state interpreting this provision? Does the state plan to challenge it? Does state plan to enact a law to provide benefits to illegal immigrants? What kind of state public benefits are (were) illegal aliens receiving? What will happen to these benefits? Please provide a list of state public benefit programs that illegal immigrants are (were) receiving and note those that will no longer be available.

2. How are counties and service providers responding to federal and state welfare reforms?

Will the state limit eligibility of qualified aliens to county public benefit programs? What types of qualified legal aliens? What benefits? Please provide a list of those county public benefit programs that are (were) available to qualified immigrants and note those that will no longer be available.

According to the Act, non-qualified aliens are not eligible to receive local public benefits. How is the state interpreting this provision? Are there counties challenging it? Please provide a list of county public benefit programs that non-qualified immigrants are (were) receiving and note those that will no longer be available.

According to the Act, illegal aliens are not eligible to receive local public benefits. How is the state interpreting this provision? Are there counties challenging it? Please provide a list of county public benefit programs that illegal immigrants are (were) receiving and note those that will no longer be available.

3. How will welfare reform affect the costs to states, counties and providers, particularly with respect to substitution of funds for withdrawn federal payments, and also with respect to other social (i.e. human) costs?

Federal programs

Nutrition programs

How much federal funding will the state lose in food stamps? Will the state / county substitute for food stamps? To what extent? From what sources? At what cost to other programs? What will be the costs for the local economy?

SSI

How much federal funding will the state lose in SSI payments? Will state general assistance payments be used to support immigrants who lose SSI? To what extent? What will be the costs for the local economy?

TANF (AFDC)

Will state funds be used to provide TANF to future qualified immigrants? What funds? How much will this cost?

Medicaid

Will state funds be used to provide Medicaid to future qualified immigrants? What funds? How much will this cost?

If the state plans to preserve Medicaid eligibility or use a state medically needy program for those immigrants who will lose categorical eligibility because they will lose SSI or TANF, what will the costs of these options be?

State and county programs

If the state will be discontinuing state benefits for immigrants, how much will it save by doing so? Will counties have to bear the cost of these discontinued state benefits? What will be the social costs of denying these state benefits? Are there estimates?

If the state/county will be discontinuing county benefits for immigrants, how much will it save by doing so? Who will bear the cost of these discontinued county benefits (e.g., municipalities)? What will be the social costs of denying these county benefits? Are there estimates?

4. What distinctions, if any, are states making to determine eligibility for welfare programs under their reforms with regard to an individual's immigration status, age, disability level or employment status?

In those cases in which the state has the option of determining the eligibility of qualified immigrants (e.g., TANF, Medicaid, state and county benefits), what criteria is the state using to distinguish among different types of qualified aliens?

Prior to the enactment of the Act, did the state or counties distinguish between legal and illegal immigrants? What kind of verification system was in place?

How far along is the state in developing verification rules (i.e., procedures for verifying that an individual is a qualified alien) under the Act?

How is the state (county) training state (county) employees to determine eligibility based on immigration status?

Please describe any problems facing the state/counties in the implementation of verification rules. Have there been any legal challenges?

5. Are there state and local plans to monitor and assess the impact of policy changes?

How does the state/county plan to monitor the effects of the Act? What kind of monitoring activities are taking place for federal programs? For state programs? For county programs?

What kind of baseline information exists for federal, state and county programs?

What kind of information will the state/county collect for federal, state and county programs? What agencies will be responsible for collecting data and tracking the effects of the law? How will the information be used?

Are state/county MIS systems adequate for tracking the effects of the law?

II. Impact of the welfare reform on immigrants, state and county governments, and the community

1. What are the direct effects of the policy changes, including health care delivery (access to care, payment for care, cost of care, and quality of care) for immigrants at the community level?

What state/county agencies have started to turn away immigrants?

What are immigrants doing to replace the benefits they have lost? Where are they turning to (e.g., other governmental levels, non-profit agencies)?

Are there any observable effects of the welfare reform on immigrants, e.g., increased use of emergency rooms, homeless shelters? Please give examples.

Are there groups of legal immigrants getting organized to protest against or legally challenge the welfare Act? Please describe/give examples.

2. What are the problems that states, counties and providers report they will face in responding to welfare reform that were previously unforeseen by federal government officials?

Is the cost of providing services to immigrants being transferred from state to county governments? To other governments?

Is the cost of providing services to immigrants being transferred from state and county governments to the community, e.g., to charity organizations?

Are there any estimates of the “hidden costs” of denying services to immigrants, e.g., babies being born to immigrant mothers who do not have access to prenatal care will represent higher health care costs?

Are there any organizations/groups that have legally challenged the constitutionality of the welfare reform? Please explain.

3. Is the state providing assistance to immigrants to become naturalized or prove qualified status?

Is state/county/other groups providing advice/assistance to immigrants who wish to naturalize?

Is state/county/other groups providing advice/assistance to immigrants who need to prove qualifying quarters?

Are there already state/county agencies exchanging information with the INS on the status of aliens?

Appendix V. Outline for State Reports

IMPACT OF THE FEDERAL WELFARE POLICY REFORM ON IMMIGRANTS IN THE UNITED STATES

STATE REPORT OUTLINE

DRAFT

I. BACKGROUND

1. Size of state foreign born population (both in absolute numbers and with respect to. total state population) (If possible, break down foreign born by citizen vs. non-citizen, and legal vs. illegal)

2. Characteristics of state foreign born population, e.g. countries of origin, date of entry, income, educational level, occupation (If possible, break down foreign born by citizen vs. non-citizen, and legal vs. illegal)

3. Geographic distribution of state foreign born population, i.e. cities/counties with highest immigrant concentrations, both in absolute numbers and percentages (If possible, break down foreign born by citizen vs. non-citizen, and legal vs. illegal)

II. POLITICAL ENVIRONMENT AROUND WELFARE REFORM AND IMMIGRATION

1. Welfare reform and immigration issues that have already been resolved (e.g. preserve TANF for qualified immigrants)

2. Welfare reform and immigration issues that have not been resolved (e.g. benefits for new immigrants and illegal immigrants)

3. The governor's position

4. The federal senators and representatives' position

5. The state legislature's position

6. Budget proposals, bill proposals and other initiatives that address welfare reform and immigration issues

    a. Groups sponsoring these proposals

    b. Issues addressed by these proposals

    c. Issues not addressed by these proposals

7. Tensions between state and counties.

8. Legal challenges

9. Likely outcome of the political process (i.e. most likely decisions regarding issues that have not been resolved)

III. DISCONTINUATION OF FEDERAL PROGRAMS FOR IMMIGRANTS

1. Estimates of the number of legal immigrants losing food stamps, SSI, TANF, Medicaid (discuss differences between different sets of estimates)

2. Cost to the state

   a. Estimates of the cost to the state of replacing federal benefits (discuss differences between different sets of estimates)

   b. Proposals to lessen cost-shifting to state

3. Cost to the counties

   a. Discuss which counties are the most impacted

   b. Estimates of the cost to the counties of replacing federal benefits (focus on most affected counties; be specific, i.e. distinguish between various federal programs: Food stamps, SSI, TANF, Medicaid, other)

   c. Proposals to lessen cost-shifting to counties

4. State's position regarding new immigrants and deeming

IV. DISCONTINUATION OF STATE AND COUNTY PROGRAMS FOR IMMIGRANTS

1. Plans to discontinue state and county benefits for qualified, non-qualified and illegal immigrants (be specific, i.e. provide a list of state and county programs that may be discontinued)

2. Plans to restructure state and county benefits as a result of the welfare reform

V. STATE AND COUNTY SYSTEMS FOR IMPLEMENTING IMMIGRANT PROVISIONS OF WELFARE REFORM

1. State and county immigrant status verification systems

   a. Current systems (e.g. verification concentrated at one state agency, verification done by counties; differences in coding across various programs and agencies)

   b. Limitations of these systems for implementing welfare reform

   c. Plans to change current systems (discuss financing)

2. State and county naturalization assistance

a. State outreach efforts (target population, types of outreach, response from immigrants, expected outcomes, INS backlog)

b. County outreach efforts (target population, types of outreach, response from immigrants, expected outcomes, INS backlog)

c. Advocacy groups and community-based organizations' outreach efforts (target population, types of outreach, response from immigrants, expected outcomes, INS backlog)

d. Plans to "institutionalize" and increase funding for naturalization assistance

3. Data to monitor the impact of the welfare act on immigrants

VI. IMPACT OF THE WELFARE REFORM ON IMMIGRANTS

1. State and local government's perspectives and estimates

2. Advocacy groups' perspectives and estimates

3. Service providers' perspectives and estimates

VII. CONCLUSIONS

RESEARCH PAPER

Potential Sponsorship by IRCA-Legalized Immigrants

Karen A. Woodrow-Lafield

U.S. COMMISSION ON IMMIGRATION REFORM

The U.S. Commission on Immigration Reform is a bipartisan commission authorized by the Immigration Act of 1990 and charged with examining immigration policy and its impact on social, economic, and community relations, on population size and characteristics, and on the environment.

Mr. Richard Estrada
Associate Editor, Dallas Morning News
Appointed by Senate Republican Leadership

Mr. Harold Ezell
President, The Ezell Group, Inc.
Appointed by House Republican Leadership

Dr. Lawrence H. Fuchs, *Vice Chair*
Jaffee Professor of American Civilization and Politics
Brandeis University
Appointed by Senate Democratic Leadership
Elected by Commissioners to be Democratic Vice Chair

Robert Charles Hill, Esq.
Partner, Jenkens and Gilchrist
Appointed by House Republican Leadership

Professor Barbara Jordan, *Chair*
Professor, LBJ School of Public Affairs
Appointed to Chair the Commission by President Clinton

Warren R. Leiden, Esq.
Executive Director, American Immigration Lawyers Association
Appointed by House Democratic Leadership

EXECUTIVE SUMMARY

A particular consideration of the Commission for Immigration Reform is the demand to immigrate to the United States by immediate relatives of aliens lawfully admitted for permanent residence and citizens of the United States. In devising the Immigration Act of 1990, policymakers considered current queues for relative categories and sought a balance among high demand, maintaining the family reunification principle, and establishment of a national level or "cap" on immigration. Given that the large backlogs of the 1980s and 1990s had not been anticipated before the 1965 Amendments to the Immigration and Nationality Act, an ongoing review of legally resident immigrants' requirements for family reunification is worthwhile. This review is timely because recent legislative reforms created sizable new immigrant subgroups (formerly undocumented residents who have been here for more than a decade, formerly undocumented workers in seasonal agricultural services, and diversity immigrants from countries adversely affected by the 1965 Amendments) and expanded admissions under employment-based preference categories.

This research focuses on demand to immigrate legally by relatives of those aliens who, having resided in an unlawful status since before 1982, legalized under the Immigration Reform and Control Act of 1986 [IRCA]. A special survey of these legalized immigrants affords analysis of household composition (including members' legal residence status and relationship to the IRCA-legalized immigrant), distribution of nonresident relatives intending to immigrate to the United States, and intentions to naturalize among IRCA-legalized immigrants. The questions addressed are: What will be the probable numbers and timing of visa petitions under second preference?[1] Assuming that immigrants intending to naturalize do so, what will be the probable numbers and timing of visa petitions under first, third, and fourth preferences, and under exempt immediate relatives categories? Unfortunately, the survey did not include aliens legalized under Special Agricultural Worker [SAW] provisions and the magni-

[1] Family preference categories under the Immigration Act of 1990 are:
1st: Unmarried sons and daughters of U.S. citizens and their children;
2nd: Spouses, children, and unmarried sons and daughters of permanent resident aliens;
3rd: Married sons and daughters of U.S. citizens and their spouses and children;
4th: Siblings of U.S. citizens (at least twenty-one years of age) and their spouses and children.

tude of requirements to be joined by their immediate family members cannot be addressed. IRCA-legalized aliens, both from general and agricultural provisions, are already accountable for substantial numbers of visa petitions for spouses and children and, as shown here, these cohorts could eventually sponsor considerable immigration of their immediate relatives. This work contributes insights to the broader question of family reunification requirements for immigrant cohorts under the Immigration Act of 1990. Several recommendations are included for improving social science and policy analyses of progression to naturalization, impacts for legal immigration of family migration, and possible interconnections of family migration with undocumented immigration to the United States.

INTRODUCTION

For a long time, combined immigration under family preference categories and immigration of immediate relatives of U.S. citizens without numerical limitation has exceeded immigration under occupational preference and other categories. In devising the Immigration Act of 1990, policymakers considered the opinions of immigration experts (U.S. General Accounting Office 1989) that setting an absolute limit on family-based immigration was not feasible. If such a limit had been imposed, the trend of increasing numbers of immediate relative immigration, only partly resulting from the amnesty programs, would have reduced the numbers of family preference visas.

Therefore, the current three-track immigration system has a "piercable cap," a limit of 675,000 that theoretically consists of 480,000 *family-sponsored* immigrant visas, 140,000 *employment-based* visas, and 55,000 *diversity* visas. Refugees and certain other aliens are outside this cap. The "piercability" stems from the artificiality of the 480,000 limit on family immigration. Immigration of immediate relatives, including spouses of citizens, children (under twenty-one years of age) of citizens, parents of citizens twenty-one years of age or older, and orphans adopted by citizens who are at least twenty-one years of age, continues to be exempt from numerical limitation. With a set minimum of 226,000 for family preference visas, the combination of immediate relatives and family preference immigration could exceed the so-called cap. Although the initial piercing had been expected for fiscal 1993 (*Interpreter Releases* 1990), fiscal 1994 marked the initial application of the minimum for family preference visas (U.S. Department of State 1993b).

An important task for the Commission on Immigration Reform is consideration of "the requirements of citizens of the United States and of aliens lawfully admitted for permanent residence to be joined in the United States by immediate family members and the impact which the establishment of a national level of immigration has upon the availability and priority of family preference visas" (Immigration Act of 1990 Section 141, (c), (1), (A)).

In devising the Immigration Act of 1990, policymakers considered current queues for relative categories and sought a balance among: high demand for visas for family members of citizens and aliens; maintaining the family reunification principle; and establishment of a national level or "cap" on immigration. Given that the large backlogs of those waiting for visas in the 1980s and 1990s had not been anticipated before the 1965 Amendments to the Immigration and Nationality Act, an ongoing review of the needs for family reunification is worthwhile. Recent legislative reforms created special needs for this assessment by creating sizable new immigrant subgroups (formerly undocumented residents who have been here for more than a decade, formerly undocumented workers in seasonal agricultural services, and diversity immigrants from countries adversely affected by the 1965 Amendments) and expanding admissions under employment-based preference categories.

Significant contributions to the issue of chain migration have drawn broadly from census data sources in *ex post facto* fashion, but relied on naturalization for a single immigrant entry cohort (Jasso & Rosenzweig 1986, 1989, 1990), focused on naturalization and sponsorship for a small sample with linked records (U.S. General Accounting Office 1988; Heinberg, Harris & York 1989), or studied selected origin groups longitudinally subsequent to immigration (Arnold, et al. 1989). (Also see Goering 1989; Arnold 1989; Teitelbaum 1989; and Passel & Woodrow 1987.)

Immigrants to the United States are a highly heterogeneous group by demographic characteristics, origin country, immigration circumstances, and reasons for emigration, so that large-scale data are really needed to capture this heterogeneity. Immigrant statistics and censuses and surveys have cross-sectional analytic value for delineating events and foreign-born populations (Woodrow 1992), but these sources are inadequate for causal or descriptive multistate modelling of initial migration, duration of residence, naturalization, and sponsorship of immediate relatives over time. Change in the

composition of the kinship network by residence may occur at each stage, and demographic factors of marriage, fertility, and mortality continue to operate. In general, analytic development of models of household and kinship organization is incomplete as there is a complex mosaic of constraints (De Vos & Palloni 1989). Compounding family network change is the additional constraint of legality of immigration to the United States to join the household or kinship organization. International migration dynamics are most appropriately studied with attention to the "families, households, or other culturally defined units of production and consumption" in the new economics of migration (Massey, et al. 1993).

The foreign-born population in the United States was estimated to have at least 17 million parents, children, and siblings living abroad in 1989, with siblings as the most prevalent type (Woodrow-Lafield 1994a; Woodrow & Peregoy 1991). Although this estimate could understate the true number, it is also an overstatement of the potential level of future immigration of immediate family members. First, as the foreign-born universe included at least two million undocumented residents, some of these residents would be ineligible to sponsor any immediate relatives (Woodrow 1992). Second, the actual number of family members seeking to immigrate to the United States is unknown. Third, some foreign-born persons residing here in 1989 would eventually emigrate, making immigration of their family members less likely or possible.

The demand of immediate family members to immigrate legally to the United States is partially reflected in petitioner backlogs for immigrant visas. These counts are available only on an annual basis rather than more frequently as might be possible if petitions were maintained on automated systems. By this indicator, demand increased markedly between January 1, 1990 and January 1, 1994, from 2.5 million to 3.6 million (40 percent) (U.S. Department of State 1994).[2] Actual demand could be higher as not all persons wishing to come to the United States would have filed petitions, given the waiting time and concern that a nonimmigrant visa might be denied if intention to overstay and reside in the United States were suspected. Most of the increase in the backlog is located in the second preference category.

[2] Petitions are removed from consular listings on receipt of immigrant visa or on failure to respond to visa notification within one year.

The 1990 Act has significantly added to the number of visas for the 2A class (issuances during FY 1994 will be close to 50% more than would have been possible under the former provisions of law), and has now virtually equalized the visa waiting period for applicants from all countries. (Previously, there had been substantially earlier cut-off dates for Mexico, Philippines and Dominican Republic applicants.) It is apparent, however, that even with the greater visa availability, the large and rapidly growing waiting list assures continued oversubscription in the foreseeable future, and the prospect of a lengthening delay between the filing of a petition and the applicant's turn for visa issuance being reached. . . .

As is clear from the section below, the major factor contributing to the greatly increased Family 2A visa demand is the filing of petitions for immediate family members by persons legalized under the terms of the Immigration Reform and Control Act of 1986, who began to be admitted to permanent residence in large numbers during 1989. . . .

> Over the next few years, as the petitioners in 2A cases become eligible to apply for naturalization, some may become citizens and thus pending 2A petitions for their spouses and children would be converted automatically into the immediate relative visa category, which is not subject to numerical limit and for which, therefore, there is no waiting period. There is potential for a possible, indeed probable, major increase in immediate relative visas in coming years, therefore, with a corresponding drop in the Family 2A waiting list. It is not possible at present to quantify this prospect, however. (U.S. Department of State 1994:A6)

For general and SAW-legalized immigrants under the Immigration Reform and Control Act of 1986 [IRCA], there were 853,382 petitions as of January 1994 for admission of spouses and children under second preference, of whom 675,626 were Mexico-born petitioners. Other countries with significant numbers were El Salvador (34,293), Haiti (26,277), Guatemala (15,689), India (13,052), and the Dominican Republic (10,645). Mexico, El Salvador, Guatemala, and the Dominican Republic were important source countries

Table 1.

Visa Petitions Filed with The U.S. Department of State by Preference Category: January 1992, 1993, and 1994

Category	January 1992 Total	January 1992 Of Legalization Beneficiaries	January 1993 Total	January 1993 Of Legalization Beneficiaries	January 1994 Total	January 1994 Of Legalization Beneficiaries

for generally legalized immigrants. Mexico, Haiti, and India were important source countries for SAW applicants.

During 1992 and 1993, visas were granted respectively to 52,272 and 55,344 dependents of legalization. In 1994, as only 32,776 visas were anticipated for such dependents, only about 140,000 spouses and children of legalized individuals would have been admitted under this special allocation, despite demand by nearly one million spouses and children.

This research focuses on demand to immigrate legally by immediate family members of those who, having resided in an unlawful status since before January 1, 1982, legalized under IRCA. The research questions addressed are: What will be the probable numbers and timing of visa petitions under second preference and, subsequent to naturalization, under first, third, and fourth preferences, and of immigrants under exempt immediate relatives categories?

This research begins to address the issue of future family immigration empirically with special survey data, for a specific cohort, for immediate relatives residing abroad, intending to come to the United States, and already living in the United States, whether lawfully resident or in undocumented status.

Ideally, the composition of immediate family networks would be studied with data compiled from individuals' applications for lawful permanent residence, but these items are not transferred for data files. In lieu of such a resource and given the shortcomings of visa petitions data, special surveys alone can yield answers.

DATA AND METHODS

Pursuant to legislative requirements to study the characteristics of aliens legalized after long-term undocumented residence, the Legalized Population Survey [LPS1], under primary sponsorship of the INS, surveyed about 6,000 respondents in 1988 on their background and socioeconomic characteristics (U.S. Immigration and Naturalization Service 1992; Borjas & Tienda 1993).[3] The Legalized Population Follow-up Survey [LPS2], primarily sponsored by the U.S. Department of Labor, recontacted about 4,000 respondents and

[3] The sampling frame did not include all applicants for legalization, such as late filers or those whose right to apply was unclear.

is a unique longitudinal data source with detailed questions affording analyses of post-legalization experiences. Woodrow-Lafield (1995a, 1995b) outlined changes in household composition (including legal residence status and relationship to the IRCA-legalized immigrant) and described the distribution of nonresident consanguineal relatives intending to immigrate to the United States. For this research, IRCA-legalized relatives' intentions to naturalize are used to set parameters on the extent to which that intending population may immigrate.

Individual-level characteristics may be analyzed as with any survey, utilizing the base weights to achieve population-level results. Because some households included more than one legalized applicant, alternative weights were necessary for accurately representing household or relatives network characteristics, e.g., the household population and the populations nonresident in the household. Family- or household-level characteristics, including relationships that are consanguineal (by blood) and affineal (by marriage), may be analyzed by utilizing the family weights, which are the base weights modified for respondents' reporting of the presence of one or more other legalized individuals within the household. Each legalized individual in a household would be eligible to report every other member of the household in the survey but would not necessarily be eligible to report the same individual family members as the respondent. These weights are used here for analyses of household composition with the caveat that all relationships are defined with respect to the primary applicant or respondent for the household.[4]

For analyzing data on nonresident relatives, consanguineal relatives may be specifically analyzed by accounting for the probability of selection into the sample and the chances that any legalized individual is eligible to report the family relative. A series of questions pertained to the legalized respondent's consanguineal relatives (parents, siblings, and children) who were not residing in the household and were outside the United States. Unfortunately, we do not know whether there were any legalized individuals outside the household who would also be eligible to

[4] As LPS1 did not acquire legalization applicant status for household members, a computer matching algorithm was used with household listings and administrative records of applicants, producing a set of variables for household legal status characteristics, i.e., numbers of legalized applicants, rejected applicants, citizens or lawful permanent residents, and "other," presumably undocumented status (U.S. Immigration and Naturalization Service 1992).

report these non-U.S. resident relatives. For parents and siblings, the family weight is assumed to account for that multiplicity. For children, a weight is used based on whether a legalized spouse is residing with the legalized respondent and, presumably, could report the *same children*. It also accounts for whether a legalized co-resident grandchild might be able to report those individuals as *parents*, and a legalized co-resident child could report the legalized respondent's other children as *siblings*. For siblings, these estimates may be overstated as other legalized individuals outside the household might be eligible to report the legalized respondent's *siblings, e.g., as children*. Legalized grandparents, and, possibly, some of the 'other relatives,' also could report the legalized respon-dent's *parents*. By examining the network of legalized individuals within and outside the household who also are eligible to report immediate relatives of the respondent with the same consanguineal counting rule, the base weight could be appropriately modified to account for multiplicity of reporting and derive more accurate estimates for the respondent's relatives abroad.[5]

To summarize this discussion of weighting and estimation of various relatives, first, estimates for household members should be very accurate. However, complete information is lacking for the most accurate weighting of nonresident relatives of the reporting respondent. For example, if an individual reported a nonresident parent living abroad, we would need to know how many other consanguineal relatives living in the United States and legalized under IRCA could also have reported that parent, with other children as the most likely. If an individual reported a nonresident sibling abroad, we would ideally know how many other siblings, parents, or children of that nonresident were here as legalized aliens. As a surrogate, the number of legalized respondents in the household is used as the multiplicity in developing these estimates of nonresidents.

Estimating the demand of immediate family members to immigrate legally involves both nonresident immediate family members, reported as intending to come to the United States, and resident ones without permission to reside permanently, each with specificity for respondent's intentions to naturalize. These results are presented in direct relationship to family preference categories and eligibility under exempt immediate relatives provisions and with

[5]See Woodrow-Lafield (1995c) for more rigorous questions and multiplicity weighting scheme in estimating the emigrant population.

specificity for the legalized respondent's country.[6] The approach is static rather than dynamically incorporating the range of possible demographic changes between the survey and occurrence of immigration.

Behavioral intentions data are admittedly subject to response error; respondents may have not considered fully their future behavior or a present decision may be changed in the course of future events. For example, fertility expectations may not accurately depict eventual fertility levels (O'Connell 1991). These levels of intended immigration and intended naturalization merit serious consideration for five singular reasons.

First, this cohort has demonstrated major commitment in their most extra-ordinary experience of living here in undocumented status for an extended period. This may portend truly high rates of naturalization and certainly implies higher rates than past measurements that confounded emigration and naturalization. There has already been extensive information exchange with relatives in the home country about the United States. Second, the survey occurred only one to two years before legalized individuals began to reach their dates of eligibility for applying for citizenship so that there may be high correspondence of intentions and behavior. Third, many legalized persons fulfilled their English and civics requirements at application for lawful permanent residence in 1988-1989, perhaps corroborating their intention to naturalize and portending expeditious processing of their applications. Fourth, legalized persons were highly concentrated geographically by state and metropolitan area, and, fifth, their familial ties to their origin countries are substantial.

Regarding the role of geographic concentration, Yang (1994) found that living in sizeable immigrant ethnic communities facilitates naturalization. His analysis also led him to support the hypothesis that unfavorable country-of-origin conditions might provide impetus for citizenship acquisition to help other relatives to immigrate to the United States. The legalized population is strongly representative of such countries as Mexico, El Salvador, and Guatemala, among others, that are unfavorable relative to the United States, i.e., with less developed economic infrastructures for adequate labor force incorporation of their working age populations.

[6] As country of birth was categorized in the LPS2 survey only as "born in Mexico" or "born in a country other than Mexico," country of citizenship is used for analyzing the experiences of legalized persons from countries other than Mexico.

PRESENCE AND FUTURE IMMIGRATION OF SPOUSES AND CHILDREN

The demographic profile of undocumented residents of the United States in 1980 diverged from that of the border-apprehended population as primarily young, male, and Mexican. Rather, the undocumented population included large numbers of women, children, and non-Mexicans (Passel & Woodrow 1984), reflecting family migration and settlement rather than merely circular migration patterns. Analysis of the initial survey of the legalized population by Woodrow-Lafield (1995a, 1995b) described the scope of family migration for the legalized population at amnesty application. These long-term residents not only had 1.8 million relatives living with them, but they also had 4.0 million relatives living elsewhere in the United States. Also remarkable is that there were an estimated 9.6 million relatives living outside the United States (Woodrow-Lafield 1995a, 1995b). Interpreting these numbers in terms of potential demand to immigrate is difficult, because, as noted earlier, these two questions were broadly stated to include all family members, that is, "spouse or partner, parents, children, brothers, sisters, grandparents, grand-children, father-in-law, mother-in-law, brothers-in-law, sisters-in-law." That is, these figures pertain to *consanguineal and affineal* relatives rather than specifically *consanguineal* relatives. Nevertheless, these statistics discount notions of transience about the population.

In 1992, four to five years after amnesty application, legalized households included more spouses and children and fewer other relatives and nonrelatives than at application (Woodrow-Lafield 1995a, 1995b). The reference group of legalized residents included 1,577,000 based on the survey. Composition by residence status is mixed, but members are predominantly entitled to reside permanently in the United States. Among the 2,519,000 persons living in households of legalized persons in 1992,[7] a very high number, 1,432,000 were described as citizens of the United States. Another 248,000 are lawful permanent residents. Another 78,000 were described as having Special Agricultural Worker status and, consequently, en-

[7] These figures are based on family weights that use information on number of legalized persons in the household.

titled to lawful permanent residence[8] and eligible for citizenship beginning in 1994. Many (129,000) are described as under "family fairness,"[9] principally spouses (41,000) and children (66,000). About 95,000 are described as having temporary visas and 385,000 fall within the "other" category. In the earlier survey, there were an estimated 686,000 individuals in this "other" category, presumably including undocumented status.

Although nearly 1.9 million resident family members have, or will have, permanent residence status, many household members may not be so entitled and might have filed visa petitions. Specifically, 136,000 spouses, 223,000 children, 30,000 parents, 130,000 siblings, and 102,000 other relatives (including grandparents and grandchildren) are estimated with status of family fairness, temporary visa, other, or missing.

With questions on nonresident children, parents, and siblings, specific for consanguineal, and weighting to compensate for multiple reporting of the same persons, a set of estimates is derived for these nonresident relatives. In 1992, the legalized population is linked to approximately 60,000 nonresident spouses, 424,000 nonresident children, 901,000 nonresident parents, and 2,843,000 nonresident siblings, totalling 4,229,000. High proportions of spouses (59.4 percent) and children (64.4 percent) are stated as intending to immigrate to the United States, but the total number is only about 309,000. Legalized respondents indicated that lower proportions of parents (25.7 percent) and siblings (25.1 percent) were intending to come to the United States, but the numbers are larger—232,000 parents and 714,000 siblings. The total number of individuals estimated as intending to immigrate is 1,254,000.

With Mexico so strongly represented in the legalization population, that country is likely to be dominant in every country-specific analysis. With these survey data, sampling variability and small numbers preclude a complete country-by-country examination of patterns. In **Table 3**, showing estimates for Mexican-born and other origin legalized respondents, the numbers of consan-guineal family members living outside the United States and intending to come dwarf those figures for relatives of legalized persons from other countries.

[8]Technically, these individuals misreported SAW status as nondenied SAW applicants were automatically converted to lawful permanent residence as of December 1, 1990.

[9]For a discussion of "family fairness," see Baker (1990) and for international guidelines on "family unity," see, Sohn and Buergenthal (1992).

Intends to Come	343,000	81,000	9,000	72,000	262,000	32,000	230,000

Six countries (Mexico, El Salvador, Guatemala, Colombia, Philippines, and Poland) account for 81.5 percent of spouses, children, parents, and siblings living abroad and 74.6 percent of those whom respondents state as intending to come to the United States. Relatives of Mexicans living outside the United States number 2,813,000, and 781,000 (about 28 percent) intend to come here to live. Siblings represent the majority of each of these categories, with an astounding estimate of 1,916,000 nonresident siblings and 454,000 siblings intending to immigrate. El Salvadorean legalized persons have about 335,000 spouses and consan-guineal family members abroad, of whom 126,000 would like to immigrate. Guatemalan legalized persons have about 139,000 family members abroad, of whom 45,000 are expected to immigrate to the United States.

Lesser levels of demand for family immigration are evident for legalized persons of Colombian, Polish, and Filipino citizenship, as commensurate with their lesser representation in the amnestied population. Altogether, remaining countries of citizenship account for 784,000 nonresident family members with 343,000 stated as intending to immigrate.

This perspective on numbers intending to immigrate relative to the numbers of nonresident immediate family members brings realism to temper any debate about explosive chain migration for legalized immigrants. By any measure, the numbers of family members expected or desired by their legalized relative to immigrate to the United States have demographic and policy significance. Nevertheless, the magnitude of this intended immigration is much less than the magnitude if all immediate family members living abroad desired to join their relatives in the United States. With the "illusory" character of sibling immigration (Arnold, et al. 1989), the absolute numbers of immediate family members that may immigrate to the United States within the next few years would be significantly lower.

INTENTION TO NATURALIZE AND FUTURE IMMIGRATION

Already into their second decade of U.S. residence, these persons appear as a solidly settled population with many having married and begun childrearing in their first five years of legal residence. Transition to naturalized citizenship is the next legal option in the route to full American status. Eligibility for greater sponsorship of family members for immigrant visas is

generally considered to be a major benefit of acquisition of citizenship. Citizens are able to sponsor unmarried sons and daughters (first preference), married sons and daughters with spouses and children (third preference), siblings with spouses and children (fourth preference), as well as parents, spouses, and children under twenty-one years (immediate relatives provisions).

Very few legalized individuals indicated that they would "probably not" (28,000) or "definitely not" (22,000) apply for U.S. citizenship. The overwhelming majority indicated that they would apply for citizenship, with most responding "yes, definitely" (621,000) or "yes, probably" (355,000). A substantial number (225,000) indicated some uncertainty about whether they would apply for citizenship. If these intentions or expectations become fulfilled, they presage a remarkable shift toward naturalization.

Presumably, those indicating they "definitely" will apply for citizenship will do so early upon eligibility and may be among those having partially fulfilled naturalization requirements. The extent of revision of intentions to apply for citizenship among those stating "probably," "uncertain," "definitely not," or "don't know" may depend on success levels of early applicants for naturalization, primarily the "definitely" category. The roles of individuals as "social actors" in negotiating INS procedures have been highlighted by Hagan and Baker's (1993) evaluation of the legalization program at eight sites nationally. During the legalization application period for both amnesty programs, response levels were moderate initially. As the legalization program proceeded without negative consequences for applicants and as knowledge about the application process, the immediate benefit of work authorization, and advocacy groups' role diffused through social networks in communities, applications increased dramatically (Hagan & Baker 1993). April and May of 1988 were the peak months of applications under general legislation and SAW legislation. After the close of the general legislation application period, SAW applications flowed in during June-November 1988 at gradually increasing levels until dramatically increasing in the final month (Baker 1990).

At the close of 1993, a year with a resurgence of anti-immigration debate (Perotti 1994), the U.S. Immigration and Naturalization Service inaugurated a new policy of actively encouraging legal immigrants to become United States citizens. In the past, the naturalization process has been complex, unfriendly, and lengthy (North 1987; Alvarez 1987), perhaps deterring any immigrants already feeling ambivalent

Table 4.

INTENTIONS TO NATURALIZE:
LEGALIZED POPULATION FOLLOW-UP SURVEY, 1992

INTENTION	NUMBER	PERCENT
TOTAL	1, 295,000	100.0
Yes, Definitely	621,000	48.0

about severing the home country tie. INS Commissioner Doris Meissner's new policy is to involve "work with private groups to publicize the advantages of citizenship and to expedite the handling of applications. . . . without lowering standards for citizenship . . . she intends to simplify naturalization procedures . . ." (Pear 1993).

Assuming that intentions to naturalize will be realized and that intentions for relatives to immigrate to the United States will reflect visa petitions, an assessment of future immigration of family members of the legalized population is possible. Shown in **Tables 5, 6, and 7** are crosstabulations of nonresident and immigration-intending relatives by intention to naturalize for all legalized respondents, Mexican legalized respondents, and El Salvadorean legalized respondents. There are approximately 1,965,000 nonresident spouses, children, parents, and siblings for

legalized persons "definitely" intending to naturalize and another 1,189,000 nonresident relatives for those "probably" intending to naturalize. Of these figures, 685,000 are relatives of "definitely" naturalizing persons intending to come to the United States. Another 333,000 relatives of "probably" naturalizing persons are reportedly intending to come.

Of family members of Mexico-born legalized persons living outside the United States in 1992, more than one million (1,115,000) were related to a respondent "definitely" intending to naturalize and another 893,000 were related to someone "probably" intending to naturalize. Slightly more than one-half million (582,000) were related to a respondent

uncertain about applying for citizenship. Of those family members of Mexican legalized persons reportedly intending to immigrate, more than one-half million were related to someone either "definitely" (373,000) or "probably" (235,000) applying for citizenship.

Among legalized individuals of El Salvadorean citizenship, the estimated numbers of nonresident relatives of those "definitely" and "probably" applying for U.S. citizenship were 162,000 and 95,000, respectively, and the implied numbers intending to come to the United States were 67,000 and 37,000.

dent parent's intentions to naturalize are shown in **Table 7** with detail on marital status and age group (under twenty-one years or twenty-one years or older). The largest number of children living outside the United States are unmarried and younger than twenty-one years despite the legalized respondent's U.S. residence for at least ten years—238,000 (56.1 percent). Of the 177,000 adult children living abroad, a slightly higher number were married (92,000) than unmarried (85,000). A large proportion (65.9 percent) of children intending to come here to live are unmarried and under age twenty-one.

Results for children of Mexico-born and El Salvadorean-citizen legalization respondents have similar patterns to those overall results. Not all of those children living

outside the United States are stated as intending to come to live here. This is the case even for the largest single category, unmarried younger children, that might be expected to be most dependent.

PROJECTING VISA PETITIONS

To project visa petitions for immediate family members, the essential components are projected numbers of family members (and spouses and children) requiring or desiring to immigrate and aspects of resident relative's eligibility as sponsor, i.e., whether resident alien or naturalized citizen. Known is that a substantial number of legalized immigrants have already filed visa petitions for substantial numbers of spouses and children, many of whom are already living in the United States under "family fairness" protection or with other temporary status. Further, the cohort has

exhibited strong levels of desire to naturalize in stated intentions and partial completion of requirements. These are the more certain contributions of the present research. To move beyond this level and project visa petitions to be filed for immediate family members, various assumptions are necessary concerning:

1. The relationship between the legalized immigrant's stated commitment to apply for citizenship and the time lag between naturalization and visa petition;

2. Unmarried sons' and daughters' transition to married status prior to immigration;

3. Transition from child to adult;

4. Spouses and children per married son or daughter;

5. Proportion married of siblings and average number of children per sibling.

Each of these assumptions will be discussed before compiling a schedule of possible visa petitions by family preference category to be filed during fiscal years 1994 through 1998.

The assumption is made that those indicating they will "definitely" apply for citizenship will complete naturalization and will do so relatively quickly, perhaps within three years. Accordingly, this timing is assumed such that one-quarter will become naturalized in 1994, one-half in 1995, and one-quarter in 1996. Anecdotal accounts suggest that the pace of naturalizations already has accelerated in such places as Miami and southern California where there were large numbers of legalizations (Cleveland 1994; McDonnell & Simon 1994). Of those indicating that they

will "probably" apply for citizenship, an overall completion rate of .75 is assumed with completion of naturalization equally in 1995 and 1996. Among those who were "uncertain," the assumption is that one-half will decide to so, split equally between 1996 and 1997. Finally, the assumption is made that one-quarter of those saying they would "probably not" apply for citizenship would do so and become naturalized by 1997. These assumptions are obviously tentative and unsupported, but helpful in devising illustrative projections.

The timing of entry into marriage varies across cultures and marriage timing for sons and daughters living in origin countries and separated from parents already immigrated to the United States might be highly unpredictable. For the purposes here, the assumption is that sons' and daughters' marital statuses at petition will not differ from marital status based on the 1992 response. Also, for children already living in legalized households for whom a petition may be filed, it is not possible to differentiate married from unmarried or even sons and daughters from sons-in-law and daughters-in-law, so all are assumed as unmarried. For purposes of estimation of second preference and immediate relatives' petitions, the assumption is made that children do not age into adulthood prior to immigration. For married sons and daughters, the assumptions are that a visa petition also will be filed for one spouse and that 50 percent of these couples will have one child for whom a petition is filed. For siblings, the assumptions are that 60 percent will be married at time of filing petition and that 50 percent of these will have one child. Even if the survey had acquired information on children of unmarried and married sons and daughters, that number might have changed by the prospective date of immigration as couples had more children or children aged to adulthood.

Finally, the assumption is made that visa petitions already have been filed under second preference for spouses and children estimated as residing in legalized households in 1992. As discussed above, figures for co-resident children are too high, including sons-in-law and daughters-in-law. Although these petitions were competing with those from dependents of SAW legalization, the assumption is made here that these individuals already received a visa during 1992-1994 or that their status will be less likely to be affected by naturalization of their immigrant sponsor. The point is moot as a new petition need not be filed because the petition is automatically shifted upon naturalization.

Despite the necessity of these various assumptions, at this point, serious doubts may have arisen about the value of the ensuing illustrations. In discussing visa petitions possibly to be filed under family preference and immediate relatives categories under sponsorship of immigrants legalized under general provisions, general patterns are noteworthy and minor differences may not be. The foundation for these projections may appear to be simplistic relative to the complex operations of the immigration system, but these have a major advantage over any others in that there are empirical estimates for immediate family members intending to immigrate and there is an empirical gauge for naturalization.

With an accounting for possible numbers of spouses and children of siblings and married sons and daughters, the overall implied number of nonresident immediate family members would be increased to 1,894,000. Siblings, with their spouses and children, could account for 1,356,000 of these. Most of the petitions ensuing from citizenship attainment are shown to be filed in fiscal years 1996 and 1997 according to assumed timing.

Petitions under exempt immediate relatives categories would increase under this scenario, especially during fiscal years 1996 and 1997. Subject to the accuracy of assumptions about coresident spouses' and children's achievement of immigrant visas, there might only be moderate increases for spousal petitions. For children and parents, annually petitions easily could be twice as high as the numbers of immigrant visas granted during fiscal year 1992.

By stipulation, there would be no further impacts for petitioner backlogs under second preference. These illustrative flows for first preference would not create any major delays, as this category is fairly up-to-date. These types of petition flows would probably mean that there would be increases to backlogs under third and, *especially, fourth,* preferences.

For fourth preference, this is particularly a concern as the *most recent cut-off date among countries of chargeability is March 22, 1985* (U.S. Department of State 1995)! Even if all of the 65,000 visas annually were dedicated only to siblings of these legalization beneficiaries, it would take approximately seventeen years to allocate visas to this many siblings with spouses and children as estimated. During that waiting period, some might decide not to migrate, but that source of attrition might be offset by others changing to decide to immigrate or by higher numbers of children.

Table 11.

Parents	259,000	27,000	232,000	192,000	31,000	79,000	72,000	9,000
Children	(C)	(C)	(C)	144,000	23,000	58,000	54,000	9,000
Spouses	(C)	(C)	(C)	81,000	18,000	38,000	24,000	2,000

Note: These estimates are illustrative. See text for explanation.

(A) Given high demand under second preference, assumption is that all unmarried sons and daughters will be transferred to petition under first preference for which demand is much lower.

(B) The assumptions are that visa petitions have already been filed under second preference, will have been largely satisfied in 1992-1994, and that legalized immigrants may be slower to naturalize and sponsor co-residing relatives.

(C) These groups are included above.

The Mexico case shows similar patterns with an implied estimate of 1,210,000 immediate family members nonresident and intending to immigrate to the United States, of whom the majority (862,000) are siblings with spouses and children. This high level of demand would mean that waiting times under this category, now nearly *twelve years*, never would be likely to improve.

These projections are of lesser magnitude for El Salvadorean legalized immigrants, with about 189,000 immediate relatives, mostly siblings with their spouses and children, implied as intending to immigrate.

Demographic population projections grounded in measurement of recent patterns of fertility, mortality, and net immigration seldom achieve high accuracy due to the likelihood of measurement error, erroneous assumptions, or even demographic behavioral shifts by time periods. These projections are unlikely to be error-free for levels and timing of family member visa petitions from legalization beneficiaries under general provisions. Similar projections have rarely been devised. [See Roney (1988) and Harper (1988) for projections of future immigration prepared for background discussion of an earlier version of the Immigration Act of 1990.] With very little empirical information, Warren (1988) estimated that there would be about 300,000 dependents of legalization beneficiaries, relying on an assumption that prior low rates of naturalization for Mexican immigrants would pertain to this special cohort. Teitelbaum (1989) rightly cautioned against assuming that past patterns of naturalization and petitioning would hold. The recent work of Yang (1994) indicates the pitfalls of merely using demographic characteristics to explain naturalization with its influence for social and economic outcomes. Entry cohorts of the past three decades also may differ from historical cohorts in that they may be lifetime migrants. Although the foreign-born population has nearly doubled in 1970-1990, emigration research has not detected any increases (Woodrow-Lafield 1995c).

Now that the appropriate caveats have been cited, the major findings can be freely noted. With these empirical portraits of immediate relatives networks, intentions to immigrate, and naturalization intentions, naturalization may be broadly sought and facilitate family migration from Mexico as well as other countries. These projections have great value for illustrating that there will be *extremely heavy demand for visas under fourth preference* from the legalization cohort. The actual level of demand may be lower if these legalized individuals had one or more siblings

Note: These estimates are illustrative. See text for explanation.

(A) Given high demand under second preference, assumption is that all unmarried sons and daughters will be transferred to petition under first preference for which demand is much lower.

(B) The assumptions are that visa petitions have already been filed under second preference, will have been largely satisfied in 1992-1994, and that legalized immigrants may be slower to naturalize and sponsor co-residing relatives.

(C) These groups are included above.

Table 13.

VISA PETITIONS POSSIBLY TO BE FILED UNDER FAMILY PREFERENCE AND IMMEDIATE RELATIVES CATEGORIES UNDER SPONSORSHIP OF GENERALLY LEGALIZED IMMIGRANTS: EL SALVADOREAN ORIGIN

Category for Petitioning	Relevant Demand Level			Possible Petitions in Fiscal Year				
	Combined	In U.S.	Intending	Total 1994-1998	1994-1995	1995-1996	1996-1997	1997-1998

Spouses	(C)	(C)	(C)	1,000	0	0	0	0

Note: These estimates are illustrative. See text for explanation.
(A) Given high demand under second preference, assumption is that all unmarried sons and daughters will be transferred to petition under first preference for which demand is much lower.
(B) The assumptions are that visa petitions have already been filed under second preference, will have been largely satisfied in 1992-1994, and that legalized immigrants may be slower to naturalize and sponsor co-residing relatives.
(C) These groups are included above.

living outside their household who, having resided here since before 1982, also received legalization.

Beyond this immediate scenario, introduction of parents as immediate relatives could lead to appearance of petitions shown here under fourth preference, under second preference, and, eventually, under first or third preferences. A pathway for sibling immigration may involve bringing in the parent, who later may sponsor remaining children (Arnold, et al. 1989). This effort is conservative about making explicit projections of that wave of petitioning as it is contingent on so many assumptions about the occurrence and timing of legalized immigrants' and parents' naturalization, among others. The accuracy of any projection diminishes as effects of erroneous assumptions compound over time. A few tentative statements are possible. Depending on family characteristics of siblings, there could be tremendous increases under second preference, possibly even before the year 2000, with many of these petitions spooling into third preference. Petitions filed under the third preference category could increase several-fold in the early part of 2000-2009.

SUMMARY

The ideal source for depicting socioeconomic changes, acculturation, fertility, and family reunification, would be longitudinal data for a full array of immigrant entry cohorts (White 1992) with linkages to original immigrants. However, the processes of sponsorship, naturalization, and family reunification are lengthy. Such a survey or administrative tracking system would be quite costly, would need to be in place for two to four decades, and would always be subject to the bias of incomplete observation of more recent entry cohorts' experiences.

This research draws on an existing dataset with detailed information about numbers, residence, and intended residence for parents, siblings, and children of an immigrant cohort. Although the study population is unique in its long-term residence in undocumented status and the effect that transition to legal status may have on the timing of bringing other family members to the United States, these data offer extraordinary insights to family migration for immigration during the 1990s. It appears that the family preference visa backlog could increase by as much as 100 percent merely as a result of the legalization of 1.7 million aliens under IRCA.

Of what value will this study be in the contemporary discussions about immigration and immigrants? May we assume enough accuracy about these predictions for policy purposes? Keyfitz (1987:237) has stated "Yet standing against this as-

sertion of the absolute impossibility of knowing the future is the absolute necessity of a picture of the future if behavior is to have any sense." For this population subgroup previously destined for an underclass life-style, the picture features massive embracing of American citizenship. Among the benefits of citizenship are greater range of eligibility for sponsorship of family members as immigrants, but political participation will be a more universally received benefit. Patterns of geographic concentration of immigrants in certain states and cities are long-standing and empowerment of these immigrants from undocumented origins in the 1970s may bode well for future urban health.

Several recommendations for federal agencies and policymakers are warranted. The recommendation with the most immediacy is that the U.S. Immigration and Naturalization Service should make an organized field effort to guarantee prompt and complete statistical records for naturalizations for 1994 and subsequent years. If the sea change suggested herein takes place, these data will be extremely relevant for social science studies of assimilation and political behavior. Concurrently with these administrative efforts, initiation of evaluation research, including naturalistic

research, on advocacy groups' role in promoting naturalization and political education is merited (e.g., Hagan & Baker 1993). To sharpen the precision of these projections and the relationship between needs for family reunification and decision to naturalize, the Legalized Population Follow-up Survey and the Legalized Applicants Public-Use File should be updated regularly during 1995-2000 to include administrative data from linked naturalization records.

A recommendation for a third wave survey of the legalized population is an obvious necessity at this critical juncture in the cohort's experience, not merely for traditional assimilation analysis, but also for informing immigration policy more fully. Only with longitudinal data on socioeconomic assimilation would the push-pull aspects of the relationship between settlement success and family reunification be discernible. Only by recontacting these individuals will there be measures of the degree to which parents, children, or siblings may have chosen to settle here as undocumented residents while awaiting an immigrant visa.

One of IRCA's main purposes, curbing undocumented immigration, apparently has not been fulfilled, based on analyses of apprehensions statistics (Bean, et al. 1990), surveys of Mexican sending communities (Donato, Durand & Massey

1992), and assessment of net undocumented immigration in the 1980s (Woodrow-Lafield 1994b; Woodrow 1992). A portion of this failure is due to continuing migration of undocumented farm workers (Martin 1994). Unrealized by policymakers and researchers may be the full extent to which undocumented migration is an integral part of legal immigration to the United States as individuals enter illegally or overstay for the fundamental reason of living with their families. With the exception of sending communities surveys, research on undocumented migration ignores its family character.

Yet family ties may be the critical link in analyzing undocumented migration patterns for the 1990s and into the twenty-first century. Failure of the legal immigration system to afford legal opportunity for family migration may lead to substantial undocumented immigration of family members of this cohort of legalized immigrants who have been settled for a decade. Another survey with similar and expanded questions on residence of family members would be valuable for studying the linkages of legal and undocumented immigration and informing policymakers concerned with enforcement of employer sanctions provisions and border control.

Finally, a similar survey of Special Agricultural Workers is long overdue. The controversy aroused by the unexpected numbers of SAW applicants probably would be relatively diminutive if the scope of undocumented and legal immigration stemming from SAWs were measurable. This population is truly elusive from the demographer's measurement view as SAWs are fully entitled to reside permanently in the United States and yet the extent to which they are resident is unknown.

Characterized as primarily Mexican and young, this population has tremendous potential for introducing wives and children into the United States initially as undocumented migrants, eventually as legal immigrants. In the present, these families may contribute to rural poverty problems (Martin 1994). These families and, to a lesser extent, families of generally IRCA-legalized immigrants, are mixed by legal status with complex implications for access to public benefits programs. Both another follow-up survey of the generally IRCA-legalized immigrants and a SAW survey are most relevant for California and the Los Angeles area with their concentrations of these individuals.

PREFACE

Temporary migrants to the United States, known legally as nonimmigrants, have grown in number and importance over the 1980s and 1990s. The Immigration Act of 1990 in particular instituted a number of changes that the U.S. Commission on Immigration Reform is evaluating for its final report to Congress in 1997. This volume represents a significant contribution to the fact-finding efforts undertaken by the Commission to understand the implementation and impact of these policies.

Scholars and policymakers working in the immigration arena have long appreciated the complexity of the different categories of permanent admissions, but only now are they turning their attention to the oftentimes linked temporary system with its rather different complexities. In this volume, leading scholars examine the nonimmigrant system's major visa categories for temporary workers and foreign students. The Commission solicited these authors' contributions to help the Commission identify major policy issues and their solutions. The introductory chapter by B. Lindsay Lowell of the Commission's staff summarizes the authors' observations and recommendations on a range of topics, from the overall system of nonimmigrant admissions to the effects of specific visa categories on U.S. businesses and workers, as well as our universities and students. The chapters here, comprising one of the first collections of scholarly studies on the topic, offer considerable scope and a solid point of departure for policymakers evaluating the nonimmigrant system.

TEMPORARY VISAS FOR WORK, STUDY, AND CULTURAL EXCHANGE:
INTRODUCTION AND SUMMARY

B. LINDSAY LOWELL

U.S. COMMISSION ON IMMIGRATION REFORM

There always have been those who come to the United States for short stays—to work and conduct business, to study, or to visit and sightsee. No single definition best describes this type of international migrant; they have come to be known for what they are not. With a few notable exceptions (e.g., holders of H-1B and L visas), they are not intending, or not permitted under the terms of their visas, to reside permanently in the United States with the full range of rights granted to "immigrants." Legally they are, therefore, not immigrants, they are "nonimmigrants" whose legal rights and responsibilities are limited to certain activities and whose stay is of limited duration.

The numbers of those on nonimmigrant visas [NIVs] coming to the United States are substantial and, unlike permanent admissions that only now are reaching peak historical levels, they have been growing throughout the century. During the first decade after the turn of the century (1901-1910), 770,000 nonimmigrants were admitted to the United States and that figure grew to 7 million in the decade following World War II.

Year	Total	Tourists
1951-1960 [1]	7,113,023	4,005,028
1961-1970	24,107,224	15,473,400
1971-1980	64,314,041	45,369,373
1981-1990	123,140,403	91,469,272
1991-1994	83,159,275	65,232,217

[1] These data are from special tabulations from the Statistics Office of the U.S. Immigration and Naturalization Service.

Two things are immediately apparent from these data: the rate of growth has been phenomenal with more than a doubling across each of the last three decades and it looks safe to forecast more than a doubling for the 1990s. The greatest share of the NIVs are issued to tourists, counted as temporary visitors for pleasure, who over the past decade have made up nearly three-quarters of all admissions by the Immigration and Naturalization Service [INS]—17 out of a total 22 million in fiscal year 1994 alone.[2] As of fiscal year 1994, the remaining approximately 5 million admissions comprise just more than 3 million temporary visitors for business and less than 2 million assorted other categories of admission, of which 764,000 include those addressed by the authors in this volume.

The U.S. Commission on Immigration Reform has been studying nonimmigrant visas under its mandate to review and evaluate the Immigration Act of 1990. That law created new admission categories and set in place regulations to control the entry and stay of nonimmigrants. Twelve authors describe here a core of temporary visas that authorize specific activities, namely the right to attend U.S. institutions of education, to work or conduct business, or to undertake study or work that comports with exchange agreements with foreign countries. These visa categories are among those with the greatest degree of rights and, with the exception of temporary visitors for business or pleasure, they are the most numerous. They also have not been subject to research by academics and have not received much systematic evaluation by policymakers. The articles in this volume address the lack of systematic study and set forth the policy implications of the available research.

[2] Tourists represent a considerable boon to the U.S. economy. In 1995, an estimated 43.5 million in-bound visitors, a figure that includes tourists for pleasure plus cross-border visitors from Mexico and Canada, spent $76 billion on travel to and in the United States. International tourism provides a net trade surplus of $18 billion (dollars international visitors spend here less dollars U.S. visitors spend outside of the United States) (communication with the Department of Commerce, U.S. Travel and Tourism Administration).

COUNTING TEMPORARY MIGRANTS

Two broad types of visa classes—(1) workers and (2) students and exchange visitors—are most central to today's concerns and are predominantly discussed in this volume (U.S. INS 1996a).

- **Workers.** The sole purpose of these categories of admission is to grant legal authorization to work in the United States. H-1B workers are professionals and highly-skilled individuals in specialty occupations. They are sponsored by employers who must attest that they will fulfill a number of wage and working conditions designed to protect U.S. workers. The visa for agricultural workers (H-2A), although numbers are small, is a constant source of debate. It requires a sponsoring employer and the job must be "certified" beforehand by the U.S. Department of Labor [DOL] as meeting a number of wage and working conditions designed to protect U.S. workers. H-2B visas for temporary nonagricultural workers (limited to 66,000 annually—although only 16,00 were issued in FY 1994) also require labor certification. D visas for foreign crewman require employer attestation unlike E visas for treaty traders and investors that require no labor market test. L visas are for intracompany transferees, workers who are employed by international organizations based in the United States.

The Immigration Act of 1990 created a number of new work visa categories: O visas for aliens with extraordinary ability in sciences, arts, education, business, or athletics, and those assisting in their athletic or artistic performances; P visas for internationally recognized entertainers and athletes, artists or entertainers on an exchange program or under a culturally-unique program; Q visas for participants in international cultural exchange programs; and R visas for religious workers. Additional workers, such as researchers, scholars, *au pairs*, and camp counselors, enter under the J visa [see below].

- **Students and Exchange Visitors).** Both the foreign student (F) and cultural exchange visitor (J) visas are intended primarily to promote both formal education and learning by experience, and both permit limited work authorization. In the case of the foreign student (F), work is generally restricted to campus with one year of off-campus practical training allowed. These visas are issued only to students who are attending INS-accepted institutions. In the case, of exchange visitors (J), whose visa may partly be governed by international agreements, some may only study, while others engage in significant work activity during their stay. The M visa is used for vocational students, who are prohibited from any employment except for postcompletion of studies and practical training.

The Number of Temporary Immigrants

The accompanying table shows three ways of counting nonimmigrants in the fiscal year 1994. The differing methods of measuring these populations demonstrate both notable administrative differences between the collecting agencies, as well as the lack of a single comprehensive measure or set of measures that count nonimmigrants and their implied year-round population in the United States.

INS admission numbers. The first column shows the most commonly cited INS figures on admissions, which are not counts of individuals but, rather, counts of the total number of *entries.* Thus, an individual with a business visa will be counted separately each time he or she enters the U.S. The number of admissions counted is consistent with the INS role in screening persons at entry into the United States and tallying each individual (entry) inspected. Clearly, admission numbers overstate the number of individuals actually involved. The count of NIV admissions or entries is, instead, the result of an administrative process.

State issuance numbers. The Department of State [DOS] counts its issuances of visas to individuals abroad, consistent with its role as the foreign representative of the U.S. Individuals apply for their visa through U.S. embassies and, when the

Counting Nonimmigrants: FY 1994

Class of Admission	Admissions (Entries)	Visa Issuances	Person-Year (Average) Populations
All classes*	22,118,706	5,610,953	1,444,319
Foreign government officials (& families) (A)	105,299	67,190	30,997
Temporary visitors	20,318,933	4,428,011	107,027
For business (B1)	3,164,099	216,825	86,235
For pleasure (B2)	17,154,834	4,211,186	810,067
Transit aliens (C)	330,936	177,815	4,520
Treaty traders and investors (& families) (E)	141,030	30,931	54,657
Students (F1, M1)	390,001	219,941	245,319
Students' spouses/children (F2, M2)	33,720	20,955	27,876
Representatives (& families) to international organizations (G)	74,722	26,525	22,773
Temporary workers and trainees	185,988	104,143	48,815
Specialty occupations (H-1B)	105,899	42,843	31,092
Performing services unavailable (H2)	28,872	25,842	8,562
Agricultural workers (H-2A)	13,185	7,721	3,328
Unskilled workers (H-2B)	15,687	10,400	5,234
Workers with extraordinary ability (O1, O2)	6,484	3,625	2,131
Internationally recognized athletes or entertainers (P1, P2, P3)	28,055	19,938	1,822
Exchange & religious workers (Q1, R1)	7,497	4,372	2,516
Spouses/children of temporary workers and trainees (H4, O3, P4, R2)	43,207	30,584	16,943
Exchange visitors (J1)	216,610	166,639	89,651
Spouses/children of exchange visitors (J2)	42,561	32,151	29,035
Intracompany transferees (L1)	89,189	22,666	20,765
Spouses/children of transferees (L2)	56,048	26,450	24,207

Sources: Admissions (U.S. INS 1996b); Visa Issuances (U.S. DOS 1996); Person-Year Populations (U.S. INS 1996a).

*Categories may not equal total because of omitted categories (e.g., fiancees of U.S. citizens, overlapping Canadian Free Trade Agreement professionals, unknown, NATO officials and professionals, and foreign media).

application is approved by the appropriate agency, DOS issues the visa for admission into the United States. But if INS admission data clearly overcount the true number of individuals who travel with a nonimmigrant visa, DOS issuance figures do not include persons from countries with whom treaties permit that the visa is "waived." Nor do all persons issued a visa necessarily use it to enter the U.S. in the year it was issued. Nor do the issuance figures reflect individuals who change from one visa to another within the United States (more on this below).

Person year population. The person-year or "average" population reflects just the portion of a year that all NIV individuals spend in the U.S. It reflects more accurately, for example, the full-time contribution of certain NIV categories to U.S. businesses: if there are 100 workers with an average stay of one-half year, they contribute only 50 person-years' worth of labor in that year. Because of the available means of measuring the person-year population, the figures will be somewhat low as they do not reflect some NIV individuals who stay more than an entire year.[3]

The table shows that INS "admissions" are significantly greater than visa "issuances," 22 million versus 5 million in FY 1994. And because the average length of stay of nonimmigrants is short, as should be expected, the person-year population is only 1.4 million. No one figure is "better" in the sense that it is more correct,

[3] The INS calculations for the person-year population is based upon comparing departure data with earlier entry records. Because not all individuals depart in a given year, especially those with longer durations of stay such as students or family members, the average stay figure will be too low. Hence, the "true person-year" population is some unknown amount greater than the one shown.

[4] Which "number" of temporary NIVs would one compare to the number of legal permanent immigrants admitted to the U.S. in a given year? INS data on legal permanent residents counts individuals and, hence, cannot be directly compared to NIV admissions data. DOS visa issuance data more nearly counts individuals like the permanent admissions' data published by the INS, but issuances overstate the year-round involvement of temporary NIVs in the U.S. economy. Also, the INS (1996b:178) estimates that as of 1992, about half of the 3.4 million illegal population were persons illegally overstaying the period of their nonimmigrant visas.

instead each is useful to describe the INS or DOS administrative burden or, in the person-year figure, one gets a sense of the average "year-round" equivalent.[4] Unfortunately, counting the non-immigrant population has even further complexity.

CHANGE OF STATUS ACROSS NONIMMIGRANT AND PERMANENT VISAS

Nonimmigrants do not always remain in the visa category under which they first entered the country. For example, a foreign student (F) may become a specialty worker (H-1B) and later adjust to permanent status.

Unfortunately, there is no reliable data readily available on the numbers of non-immigrant changes across NIV statuses, such as the F to H-1B example above. In lieu of such figures we can only crudely estimate about how many Fs end up as H-1Bs and, ultimately, in a permanent status. One possible source of information is INS records on change of status made within the U.S. that suggests that perhaps as much as two-fifths of those changing status to H-1B in FY 1994 previously held a nonimmigrant visa.[5] In any given labor market that portion may be much greater depending upon the job possibilities (see Michael Smith in this volume).

Data on adjustments to legal residency allow us to gauge the portion of NIV holders who transition onward to permanent status. In this volume, David North estimates that cultural exchange visitors (J) and foreign students (F) have low rates of direct adjustment, with an estimated one-sixth of Fs adjusting to permanent resident status.[6] Both the intracompany transferees (L) and skilled workers (H-1B)

[5] In FY 1995, there were more than 26,000 changes of status to H-1B, out of a possible 65,000 H-1B approvals. Most were from the foreign student NIV (F) (Special tabulations of INS district offices made available to the Commission).

[6] A crude, lower-bound estimate places about one-fifth of foreign students moving both from F directly *and* indirectly through H-1B to any permanent status (calculated from North's F and H adjustments to LPR status; and 1995 INS Service Center data [F to H] over DOS of F issuances five years previously [F to H status change]).

have substantially higher adjustment rates—a little more than one-fifth of transferees and possibly as many as four-tenths of H-1B workers adjust to permanent resident status. These relative rates are what might be expected. Students may have low adjustment rates because, once their training is finished, their purpose for staying is finished as well. And, as the number of students is substantially greater than that of specialty workers, it is not possible for a high proportion of students to adjust into the numerically-limited employment categories.

By contrast, specialty workers (H-1B) and intracompany transferees (L) are exempt from provisions precluding issuance of NIVs to those who intend to reside permanently in the U.S. Some of these workers enter with temporary work visas to bridge the period needed to obtain permanent immigrant visas. In other cases, employers choose to retain temporary workers, to capitalize on skills learned in the U.S.

It is also interesting to note the permanent categories into which nonimmi-grants adjust.[7] Although nonimmigrants adjust into all permanent resident statuses, as of FY 1994 foreign students (F) were most likely to adjust into the following permanent visa categories: exempt spouse (47 percent) and skilled employment-based preference (EB-3) (44 percent). In contrast, about one-half of both specialty workers (H-1B) and exchange visitors (J) adjust through the skilled employment-based preference, while intracompany transferees (L) adjust into the U.S. primarily as priority employment-based workers (EB1) (81 percent). Perhaps it is no surprise that one-third of the H-1B adjusters report science or engineering occupations, while 90 percent of intracompany transferees (L) report executive or administrative occupations at adjustment. On the other hand, neither foreign students (F) nor exchange visitors (J) fall clearly into any occupational grouping. Several articles in this volume assess this process of moving from one status into another.

[7] Special tabulations by the Commission of only principal visa holders from the INS FY 1994 permanent admissions public use data.

Changing Status Not a Problem. Charles Keely makes the case that the process of changing status and adjusting to permanent residency is a natural consequence of the U.S. admissions' system and the global economy. He believes the process is not detrimental and is, in fact, a favorable phenomenon. Papade-metriou and North recommend that the adjustment process be recognized and, as they regard adjusters as presumable successes who have gained valuable experience in the United States, they, too, view the process in a favorable light.

These authors recommend some type of dual-track temporary visa that acknowledges the process of adjustment to permanent residency status. The details of how such a visa would be granted and its terms are not spelled out, however. If a special visa were not created, the decision to grant permanent residency to an individual might somehow take into account their experience as a nonimmigrant.[8] And if there remains a concern about the ease of shifting status, North recommends that a sizable fee be assessed against the employer who petitions for a permanent visa.

Length of Stay. Despite the overall positive aspects of this process of change, several authors recognize potential abuses by individuals whose initial intent in obtaining a NIV is to remain permanently. They imply that reducing the length of stay permitted on a NIV would reduce such abuse. Such shortening of the time frame for action would be consonant with the purpose of a temporary stay, would acknowledge that some NIV stays with renewal options, etc., are too lengthy, and would lessen the possibility of individuals acclimating to the U.S. and drifting from one status to another. Both Papademetriou and Gregory DeFreitas recommend that the stay permitted on working visas (H-1B) be reduced, to three and two years, respectively, with no possibility of renewal without return to the home country. Barry Chiswick and North recommend that to keep individuals from endlessly pursuing education (often as a

[8] North implies that, if a point system was created to screen applicants (see text below), additional points could be granted for relevant experience.

screen for unauthorized employment), student visas (F) be closely monitored with regular evaluations of academic progress.

Return Requirements. Another way in which to deal with the changing status phenomenon might be to require that, at the end of their temporary stay, NIV holders return to their country of origin for some period of time. Only after that return requirement was finished could the individual reapply for a U.S. visa. This is a requirement for some cultural exchange visitors (J) and could be applied to other NIVs as well. North, for example, recommends an option that would impose a two-year return on foreign students. Keely, while not advocating a return requirement for foreign students, makes a clear distinction between foreign students who pursue higher education with independent financing and those who receive funding from their home government, international organizations, or scholarship programs intent on aiding international development by education. If return requirements are put into place, he argues compellingly that return should be required only of students whose education is intended to benefit their nation of origin. DeFreitas would require working H-1B visa holders to leave the U.S. for one year after their temporary stay ended.

TEMPORARY WORKERS IN A POSTINDUSTRIAL ECONOMY

Both Demetrios Papademetriou and Charles Keely present the big picture of the role of temporary foreign workers in a postindustrial economy. Global firms and fast-evolving, knowledge-based products demand a very different perspective than yesterday's. Today's knowledge industries must be fast moving and their product, unlike yesterday's industries, does not become more expensive to produce as raw materials are used up—a process that takes time. By extension, today's knowledge industries cannot treat all workers as essentially interchangeable; training takes time and may never fully compensate for a foreigner's specialized experience in a desired foreign market. Contemporary knowledge industries face steep, up-front development costs that are recouped by volume (and ever cheaper)

sales, and the race for market share goes to those who get their product out first. Getting the right worker with specific qualifications for short-term needs can be very important in these competitive marketplaces. Examples abound in pharmaceuticals, electronics, or computer software development, but the pace of the marketplace often is replicated in traditional industries like automobile manufacturing that market state-of-the-art autos on short cycles and produce just-in-time.

Positive Role of Foreign Workers. Against this backdrop, some believe restrictions on high-skilled temporary workers could well have adverse effects on the U.S. economy and its resident workforce. Keely argues that the genesis of those advocating severe restrictions is rooted, not only in a profound misunderstanding of the reality of post-industrial economies, but in the evolution of nonimmigrant policy and procedures. He traces NIV history from a passive admissions policy: employment-based immigrants entered unless the Secretary of Labor took steps to prevent entry based on a complaint or large level of petitioning by a single employer. However, after the Immigration Act of 1965, a more active process was introduced that Keely says:

> . . . institutionalized anxiety about the impact of immigration on the labor force. Dimensions of the economy were pitted against one another in an adversarial way, as if labor force development is a zero sum game.

The legal profession and adversarial procedures have become integral parts of the admissions' system for both permanent applicants and nonimmigrants and Keely believes "it is virtually naive to suggest that it could be otherwise;" however, the heritage of this adversarial mentality often is based on the assumption that the labor force is static like a fixed pie. Keely argues the restrictive and bureaucratic procedures that result from this heritage can run against the needs of a modern economy for flexibility, timeliness, and access to a global labor force. Most of the authors would concur that an emphasis on facilitating employers' *genuine* needs is in the national interest and can make the

U.S. more globally competitive to the benefit of U.S. workers.

Areas of Concern. Nevertheless, these chapters raise areas of concern, especially with the number of H-1B workers involved and the special features of their employment that may contribute to some adverse impacts. As David North argues:

> . . . when there are concentrations of alien workers in a given labor market . . . there are likely to be problems of labor market distortion lower than normal wages, higher than normal unemployment. These problems are likely to be aggravated when the workers involved have few rights or few perceived rights (such as the H-2A farm workers and the newly-arrived Indian programmers).

Where North argues that the long-term impact of the student and cultural exchange categories are "bland or scattered," he classifies the skilled worker as having an impact "of some concern." His concern is bolstered by "plenty of noise" in certain occupational sectors; North pays particular attention to the fields of science and engineering that are believed to already have an oversupply of workers (North 1995; see also Anderson, 1996).

Gregory DeFreitas also articulates concerns about the number of foreign workers now in high-skilled U.S. occupations and argues that all—permanent and temporary—skill-based admissions be closely regulated. Although many economists argue that immigrants should be selected on the basis of their skills, they seem implicitly to assume either that highly-skilled workers are not adversely impacted by increases in immigration or that any impacts are small and quickly responded to by U.S. professionals without broader ramifications. There are, however, a few studies that do find the possibility for direct competition between foreign and U.S. professionals, especially among permanent residents, and DeFreitas notes that:

> . . . in an era of widespread corporate downsizing, claims of skilled labor shortages have raised growing suspicions. Unlike the early 1980s, the majority of per-

> manent layoffs now are occurring among college-educated employees. The share of job losses accounted for by those earning at least $50,000 has doubled since the eighties.

If wage depression does occur among skilled workers it might be associated with lowered demand and less opportunity for upward mobility of low-skilled U.S. workers. And there may be further complications in relying on skilled foreign labor that are raised by use of H-1B workers.

DeFreitas argues that the current Labor Condition Application [LCA] does not adequately protect the U.S. worker from being replaced by an H-1B; nor does the LCA hold the ultimate employer responsible for the attested wage rates and working conditions of the H-1B worker. This can encourage the growth of job shops with the attendant potential for misuse of the H-1B program. Further, DeFreitas believes the program itself can sew the seeds for increasing outsourced jobs abroad because the H-1B worker, once trained in the U.S. and familiarized with corporate needs, becomes an ideal jobber when he or she returns home. He argues that "what is needed now is more, not less, limitation on and monitoring of skill-based temporary immigration programs." These themes surface not only from DeFreitas' close observation of the labor market and the limited number of official documents and media coverage that deal with foreign workers, but also in two field studies reported on in this volume: both were conducted on the H-1B labor force in 1994-1995, two years after the implementation of the Immigration Act of 1990 and in globally competitive industries undergoing downsizing and restructuring.

Houston Field Study. Jacqueline Hagan and Susana McCollom undertook a study of H-1Bs employed in about thirty computer programming and research organizations in the Houston metropolitan area. Their research found circumstances consistent with the nature of spot shortages that occur in fast-changing, globally-responsive businesses, at least in the case of the highly-specialized skills required in Houston's research sector:

> Given what looks like a robust labor market in Houston for com-

> puter analysts and programmers, and for high level researchers in faculty positions, we were initially at a loss to explain what we encountered in the field: unemployed and underemployed computer programmers and analysts and an increasingly tight labor market for faculty positions.

Yet, employers reported a need for H-1B workers because they were unable to find U.S. workers. A spot shortage appeared to be indicated in the case of positions at university or private research settings which have gone "unfilled for months or years" because a very specific set of skills, say in robotics development, is sought. In such instances the H-1B workers, some of whom were research assistants in such settings, provided a valuable resource for the U.S. with seemingly little adverse impact on U.S. workers.

On the other hand, the computer programming field has developed an outsourcing strategy that involves job shops that take on the production work of larger software development firms, pointing to potentially adverse outcomes in the H-1B program. These shops permit the larger firms to get production work done as needed without employing year-round employees. Unfortunately, the authors suggest, the incentives for job shops to be competitive in lower-end programming work can lead to adverse outcomes for the H-1B worker and for similarly-skilled U.S. workers. In the case Hagan and McCollom elaborate on,

> H-1B workers were recruited abroad and, once in the U.S., were paid less and placed in poorer working conditions than similar U.S. workers in the same organization. And the skills they needed were not necessarily those for which the employer advertised. This research suggests systematic violation of the employers' H-1B attestation that could place H-1Bs in unfair competition with U.S. workers with the requisite education, of whom there are many in the Houston area.

San Francisco Field Study. In field work on high-tech workers, Michael Smith asks, "Who is the employer?" and "What is the problem?" His study gathered qualitative data through open-ended interviews with "all parties involved in the recruit-

ment, employment, and regulation of foreign nonimmigrant skilled workers" (i.e., employers, workers, and various representative groups). Most of the H-1Bs had master's degrees and most of these foreign workers had received that degree in the U.S. while on an F-1 student visa (one estimate is as many as 70 percent). Employers reported that because technologies change so rapidly, they must hire applicants who already possess the specialized skills the employers require.

Several computer consulting firms studied had changed their use of visas in response to the tightening of wage compliance and stricter B-1 enforcement. The consultants reported that the longer duration of stay permitted by the H-1B visas is reducing the number of workers who return to their home country and increasing those who stay permanently. Oddly, these consultant were critical of the client firms that hired them for not investing in the training of an available labor pool of U.S. workers displaced by the corporate downsizing of recent years. For their part, U.S. workers believed that the Immigration Act of 1990 encouraged the expansion of foreign-run consulting firms that now underbid U.S. consulting firms. All parties agreed that H-1Bs received lower wages in consulting firms than their U.S. counterparts. While industrial restructuring and, more particularly, corporate downsizing are the major forces behind poorer working conditions for laid-off workers, both appear here to be reinforced by the related growth of subcontracted work. When job shops are used as middlemen to provide low-cost production programmers to client firms—private or public—the potential for abuse and displacement may well increase.

At the same time, U.S. workers in Smith's study argued that the just-in-time skills employers claim they require is not, in fact, consonant with the prevailing practice to train and the time taken to familiarize oneself with a new client firm. For their part, professional and union associations reported three problem areas in the H-1B visa: the ultimate employer is masked; the workers have little security and thus tend not to complain about depressed wages; and the prevailing wage calculation produces low average wages.

In contrast, the study found that H-1B workers in biotechnology firms pre-sented a different picture. Here Ph.D.s recruited internationally (in a search process that might take as long as six months) were hired as project managers and postdoctoral researchers. Findings here do not indicate wage depression or job displacement. In the university teaching and research settings, H-1Bs tended to be hired as faculty or postdoctoral researchers. But, while faculty hires required a substantial investment in hiring the very best, postdoctoral student positions were more plentiful and appeared more likely to misuse the H-1B visa. As some argue, such findings suggest that foreign postdoctoral students dominate these positions while many U.S. graduates, deterred by the low wages, look for work in the private sector.

Comments on the Current System

Having identified both strengths and weaknesses of the current system for admitting foreign workers, the authors present a range of recommendations to address problems in the current system. For the most part their recommendations focus on the H-1B.

DeFreitas recommends greater control and more protections, measures that go even further than those advocated by DOL (Reich 1995). He would restrict working visa applications to DOL-determined shortage occupations, require an application fee, reduce the permitted stay to two years, with a minimum one-year probation from applying for permanent residency following the stay,[9] apply additional employer attestations that protect U.S. workers (provisions against layoffs, lockouts, strike, and demonstration of "substantial and continuous efforts to fill the jobs for which they currently desire foreign workers"), and apply H-1B regulations to all work sites where H-1Bs are working. His recommendations would apply to all working visas.

[9] This recommendation is intended to reduce the waiting period for permanent residency applications and to reduce employer dependency.

All the authors concur in the spirit of the latter recommendation aimed at keeping the ultimate employer, not the middleman, responsible. As Smith says:

> Regulatory and enforcement mechanisms should focus on the "real employer," i.e., the clients of contract workers, including holding them accountable for paying prevailing wages to non-immigrant workers.

Both Smith and Hagan call for increased DOL workplace monitoring efforts, targeted especially on so-called job shops, and particularly on prevailing wages. Otherwise, perhaps because their field work found the most blatant visa violations only in the out-contracting sector, they do not advocate reforms as extensive as those DeFreitas proposes.

Smith and Hagan also found substantial frustration among college and university employers with the H-1B visa conditions and with the unrealistic prevailing wage determination in their sector. Because of the importance of this sector, Hagan recommends the "creation of a special H category for research universities and institutes." While Smith concurs that an "H-1C" visa should be created, he also found some evidence that foreign postdoctoral students sometimes compete with natives, creating a "potential for general wage depression [and] abusive working conditions." Therefore, he recommends that the university visa be restricted to "full-time, tenure-track, teaching and research occupations." The resources freed up from close monitoring of these truly select workers he would allocate toward the postdoctoral researchers.

North recommends two possible roads to reform: making a moderate number of changes in the existing system; or substantially reworking the entire administrative and visa system. At the least, he argues for a mandatory return ticket for all temporary visa holders, elimination of employer petitions for groups of H workers, the elimination of the H-2 visa, and the introduction of labor standards into the exchange (J) visa (or better yet, moving J-workers into the H worker visa).

Reconfiguration of the NIV System. North's more substantial reform propos-

als involve reconfiguration of the visa categories, revised screening methods that would facilitate the process with due attention to protections, and reform of the governmental administrative apparatus to manage the entire system more efficiently and effectively. North believes several basic principles should underlie a substantially reformed temporary visa system: the number of visa categories, as well as the number of government agencies involved, should be limited. Instead of eight student and working visas, he recommends four visa types: for students; for temporary workers; for intercompany transferees; and for H-type workers on a track for permanent residency, a transitional visa. Like Papade-metriou, he believes enforcement efforts should be at least partly funded by user fees, should be more efficient, and should target certain countries or employers with far more scrutiny. To ensure that individuals leave, he calls for a required, lifetime, round-trip ticket for *all* temporary visas.

Although Papademetriou finds that the current visa categories satisfy "one or more of [the basic] requirements" for a temporary worker system, he also recommends a substantial reconfiguration of the selection and management systems. The restructuring he considers would move most administrative functions into the INS and couple a rigorous, though simple, points test of foreign workers with a more stringent employer attestation and enforcement regime. The points test he outlines would be applied to potential workers, including H-1Bs, to select those least likely to compete with low-skilled Americans and those whose skills and productivity are most likely to promote U.S. economic interests: employer selection would be constrained to this pool and they would be required to file an attestation. Bypassing the cumbersome and time-consuming aspects of a certification system (in the case of H-2A and H-2Bs) could well facilitate employers' access to workers (who meet the minimum points test). An attestation requirement likewise could facilitate the process and serve as an enforcement tool for what should be (for his recommended system to work best) a renewed emphasis on the enforcement of the conditions agreed upon for the work authorization.

Temporary Workers in Agriculture: Are More Needed?

Predictably, in agriculture, the role of middlemen and its potential for adverse consequences surfaces again with the H-2A visa. Philip Martin covers the economics of labor in the agricultural industry, describing its historical reliance on cheap, foreign labor. It is a story, however, that differs from the others in this volume.

There have been calls for an expanded and simplified H-2A program in agriculture, partly by some who want to rationalize the exchange of labor be-tween Mexico and the United States. However, those most interested in the expanded/ simplified version of a new guestworker visa are the growers of crops that are harvested by hand. Much of the foreign labor upon which growers of fruits and vegetables rely is unauthorized. There are extremely few legal nonimmigrant (H-2A) visas in use by growers who dislike the paperwork, the number of labor protections and requirements, and the federal control of that program.

There is, of course, a long and complex history of the demand for seasonal agricultural labor and the employment of authorized and unauthorized workers throughout the southwest. California agriculture, in particular, has played a special role in most of the twentieth century debates involving Mexican immigration. The controversial *bracero* program brought more than 4.5 million Mexican workers to U.S. farms—more than one-half to California alone—between 1942 and 1964. California farmers were among those employers who most strongly argued that the price of their support for the employer sanctions provisions of the Immigration Reform and Control Act of 1986 [IRCA] was an assurance of continued access to legal Mexican workers. Congress established the Replenishment Agricultural Worker [RAW] program that would authorize the entry of workers in the event that they were needed. If IRCA proved to be successful, it could conceivably cut off the ready supply of unauthorized workers and the Departments of Labor and Agriculture were charged with determining if a shortage of seasonal workers developed. North reports that

no shortage was found during the life of the program and no RAW work authorizations were given.

When Operation Gatekeeper along the Mexican border was launched in 1994, and again, when Congress moved toward tightening restrictions against illegal immigrants in 1995, California farmers sought to secure legal guestworkers. Martin notes that the debate frequently is framed by contrasting extremes—farmers assert that there are likely to be labor shortages, farmworker advocates argue that 10 to 30 percent of farm-workers are unemployed even during peak seasonal demand and there is no need to bring in more workers. Congress has considered, and may well consider again, establishing an agricultural guestworker program that is either an altogether new visa or a simplification of the existing H-2A program.

Has stepped-up border and interior enforcement actually reduced the availability of legal seasonal laborers? Californian growers Martin surveyed in the fall of 1995 virtually all report an ample supply of farm workers. He argues there should be visible labor market responses, such as rising wages or increased applications for H-2A workers, before such programs should be considered seriously. Yet, more than 90 percent of the responding farm employers reported no trouble finding sufficient seasonal farm workers in 1995; the handful of employers who reported shortages generally did nothing concrete to obtain additional workers, such as raise wages, ask the state employment service for workers, or apply for certification to bring foreign workers into the U.S. under the existing H-2A program. Martin finds that the evidence and the survey data support the U.S. Commission on Immigration Reform's unanimous position (U.S. CIR 1995) that no new guest worker program is needed at this time for California agriculture.[10]

[10] If there were to be labor shortages that put upward pressure on farm wages, Martin argues, consumers would likely see little increase in the costs of fruits and vegetables as wages make up a minute fraction of retail prices. In the short-run, higher wages might attract more year-round and more productive labor. Over the longer-term, he believes growers could even reduce the demand for labor with capital investments in new technologies and engineered crops and possibly reduce retail prices.

Opinions on the H-2A visa tend to be strongly held. Indeed, North, who would abolish the program in its entirety, states, "This program simply transfers funds from American farm workers to agri-business; it is small but a disgrace."

On the other hand, Papademetriou does not find an agricultural worker program in and of itself objectionable. He proposes that:

> . . . serious thought be given to replacing this category with a program that focuses on enhancing employment opportunities for U.S. agricultural workers, while acknowledging the unique nature of that labor market, its binational (primarily Mexican) composition, and the historical (and future) reliance of that sector on a foreign workforce.

At the time of the writing of this volume, his proposals for reform of the H-2A were still in development. However, it is possible to speculate about a range of options, such as levying a user fee for a U.S. workers' fund, testing the labor market for shortages as DeFreitas suggests, and, both to facilitate growers access and enhance monitoring, bringing into the process multiple actors, such as employers, the Mexican government, and a greater INS and DOL enforcement presence.

Martin argues pragmatically that the current program may be better than some of the alternatives being considered. He concludes that:

> . . . the H-2A program may . . . not be perfect, but it does look better than the alternatives . . . and I find it hard to believe that, given the history of controversy surrounding employment of foreign workers in U.S. agriculture, the U.S. will in the late 1990s introduce an attestation program for alien farm workers.

Recall that the H-2A application requires a vigorous up-front DOL screening and must meet each of several wage and U.S. worker protection requirements: the details of the visa application must be certified prior to entry into the U.S. Simplification of the H-2A program could involve

changing the certification to an attestation that is not vigorously screened up-front and comes into play only if there is a visa violation reported after the worker begins. If Congress did introduce an attestation program, Martin would recommend levying a sizable user fee to be invested in a workers' training fund. Indeed, he argues for serious consideration to the development of additional safeguards if an attestation-like program were introduced.

FOREIGN STUDENTS

As Barry Chiswick notes, "The United State is a magnet for foreign nationals seeking university level and advanced (graduate) level training." Chiswick presents a profile of foreign students based on administrative data and an annual survey of universities. He argues that the flow of new students has not increased significantly since the 1960s, but the stock of students has risen due to longer stays.

Several authors in this volume offer reasons why foreign students are a benefit to the U.S. university system. Keely argues that the number of foreign students can be taken as evidence that U.S. colleges and universities are a successful service export industry with significant global ramifications:

> The American college and university system is a valuable service export that has down-stream spinoffs as alumni/ae of U.S. schools move into responsible positions in the private and public sectors of their societies.

Barry Chiswick notes that the U.S. most likely will remain a magnet for foreign students, especially in the sciences. Still, foreign students' share of the total student body is very small and he believes that there should not be a lot of handwringing over its possible adverse effects, most certainly not among undergraduates. While foreign students are only a small portion of the general student body, a little more than 3 percent in 1995, Chiswick reports that nearly one-half of all foreign students are in U.S. graduate programs where they make up more than 9 percent of the entire graduate student body in all disciplines.

The U.S. reputation for graduate training is well known and many foreign students come here to pursue degrees in science and engineering [S&E]. Chiswick points out that, not only is the U.S. at the forefront of research in the scientific disciplines, but the jargon of mathematics and science are both universal and often written in English (while the humanities require knowledge that is highly specific to a culture or national setting). Beyond these commonplace observations, however, foreign graduate students are an integral part of the teaching and economic functions of the modern university: they learn by teaching and doing research; they provide a critical tutorial function; and they constitute a needed supply of research assistants. With a relative shortage of native-born seeking advanced study in science, he notes that foreign students step in and help keep instructional costs low and maintain the preeminence of U.S. university-based research.

Jagdish Bhagwati and Milind Rao specifically address the foreign Ph.D. graduate in the sciences and engineering disciplines where they are concentrated. These numbers have increased since the 1950s until, as of 1990, about one-third of all U.S. university-awarded S&E Ph.D.s went to foreign students. The authors argue that enrollment and graduation data support the notion that the increase in foreign graduate students results from the greater number of high-quality universities globally and the lure of flagship U.S. universities whose very leadership relies on government-funded S&E education. For example, the pool of S&E undergraduates has grown enormously in many Asian countries and the level of research and training at the best foreign colleges has come to be highly regarded. India graduates 25,000 bachelor-level engineers each year, of whom only 2,000 graduate from the elite Indian Institute of Technology [IIT]. Yet, the authors report that eight-tenths of the Ph.D.s awarded to Indians in the United States went to these elite IIT graduates. They note that "other nations 'brain drain' is our 'brain gain.'"

Also, the large proportion of foreign S&E students can be explained by the combination of the availability (pool) of highly qualified students, the choice of a field of study, and the funding structure of advanced education in the United States.

They observe that, whereas only 1 percent of the entering class in the professions receives university funding, and 20 percent of those pursing a Ph.D. in the humanities and education, 70 percent of all S&E students report the university as their primary source of funding—and fully 81 percent of foreign Ph.D. students, most with limited rights to work in the United States and often with few personal resources, are in S&E programs.

Indeed, large differences in the availability of university funding by discipline may explain part of the apparent advantage foreign students have over U.S citizens in terms of securing university funding. Bhagwati and Rao note that more than one-half of African American Ph.D.s in particular are concentrated in education, a field in the humanities with low levels of university funding, which heavily affects statistics on African Americans.[11] Frank Morris in this volume argues, nevertheless, that even in education 12 percent of African Americans report being *primarily* funded by the university as compared to 28 percent of foreign doctorates. He and North share a concern that native and minority graduate students are not financed as readily as foreign students. Otherwise, North reiterates his belief that the general impact of foreign students on natives and minorities in graduate schools—or in the labor market—is small. The specific areas of impact and the appropriate policy response both deserve more study.

There is evidence that U.S. universities prefer minority doctoral applicants over foreign applicants (North 1995:49), and other trends make it difficult to assert direct and substantial minority displacement in graduate schools. Bhagwati and Rao note that the pool of African American students with S&E bachelor degrees declined slightly over the 1980s, although 14 percent of native African Americans opt for S&E degrees (where the proportion relying primarily on university funding is the same as that of other students). Yet interestingly, while the total number of Ph.D.s awarded to African Americans

[11] In 1993, 9 percent of all Ph.D.s granted in education were received by African-Americans, more than four times the percentage of African-American S&E Ph.D. recipients, and more than double the percentage (4.2) of all African-American Ph.D.s (Thurgood & Clarke 1995:23).

continued a two-decades-long decline, Bhagwati and Rao report that total S&E Ph.D.s awarded to African Americans increased through 1990. Because the number of *all* natives in S&E Ph.D. programs has remained constant for roughly two decades, some observers conclude that the lack of more native S&E Ph.D.s, of any race or ethnicity, is due mostly to the available pool of resident S&E students coming up through the ranks (NSF 1996:2-15).[12]

Clearly, there is some agreement between several of the authors and none strongly argues for a ceiling on foreign students. Bhagwati and Rao conclude that foreign S&E graduates are a boon and that their availability may actually expand S&E capacity. Nevertheless, it is acknowledged that the potential for abuse of the student visa exists: Chiswick recommends that carefully-crafted administrative procedures be put into place and given a chance to curb abuse of the foreign student visa, particularly by those who fail to pursue their academic studies. The specific administrative procedures he recommends would require that an appropriate college or university representative regularly certify that its foreign students are making satisfactory progress toward their intended degree. North, in turn, suggests strengthening oversight of the educational institutions that petition for the right to admit nonimmigrant students. To strengthen the principle of temporary stay, both North and Chiswick consider requiring return conditions, calling for a prepaid return airline ticket for each applicant. Chiswick also recommends baring the issuance of any visa to persons who violated the conditions of a previous visa.

North and Morris share a concern for the possibility that foreign students may have some adverse effects for some U.S. residents in certain fields of graduate study. Morris' argument points to a long chain of causal events starting with a decline in

[12] The total number of bachelor degrees awarded in the natural sciences actually declined through the 1980s; increased and then fell off in mathematics, computer sciences, and engineering; and only the social and behavioral sciences have showed an increase in bachelor degrees since the late 1980s (NSF 1996:2-15). Bhagwati and Rao also note that many S&E undergraduates may choose employment or pursue careers in more lucrative professions.

direct federal grants in the 1970s to today's university controlled distribution of research and teaching assistant positions. The major problem he argues is that colleges and universities are now providing direct funding to foreign students that could be spent instead on minority, and particularly African American, students. He advocates that an "American incentive computation" be made in every state or federal contract with a university that supports doctoral students: points would be given based upon the proportionate representation of minority students. North speculates about the balance of U.S. government monies spent on foreign student education and, likewise, considers regulation on funding. He suggests a ceiling on the proportion of foreign graduate students funded by federal research grants.

CONCLUSIONS

On balance, these articles argue that the nonimmigrant system meets a wide variety of goals that are in the national interest. At the same time, they raise serious questions about specific visa categories and some of the regulatory mechanisms that govern an individual's temporary stay. Readers who go carefully through each chapter will find a wealth of information not covered in this introduction and summary. Those steeped in the complexity of the system may wish for more detailed attention to some mechanisms, things as nuanced as how and where employers advertise for residents before applying for a nonimmigrant worker. However, these articles add to our understanding of the overall effects of the nonimmigrant visa system and provide guidance regarding policies to strengthen its operation.

SKILLED TEMPORARY WORKERS IN THE GLOBAL ECONOMY:
CREATING A BALANCED AND FORWARD-LOOKING SELECTION PROCESS

DEMETRIOS G. PAPADEMETRIOU
CARNEGIE ENDOWMENT FOR INTERNATIONAL PEACE[1]

Twentieth-century America, no less than the America of earlier times, has benefited greatly from the presence of foreign workers. Even in the 1950s, when fewer immigrants entered the United States than in any decade since, the U.S. economy may have been far less self-sufficient in terms of both talent and brawn than is generally acknowledged. For example, in addition to the talent brought in through the family and modestly-sized employment categories, as well as that decade's refugee inflows, there were the large-scale "immigration" of Puerto Ricans and the even larger *bracero* program for U.S. agriculture, which admitted between 300,000 and 400,000 Mexican workers a year throughout the 1950s. *Braceros*, who were classified within the immigration system as temporary workers or nonimmigrants, provided a nonresident labor force for an industry that had faced war-time shortages. Although the *bracero* program was ended in the mid-1960s, other programs for temporary workers have continued to supplement the flow of permanent residents, contributing to the robustness of a complex U.S. economy that spans the gamut of capital, knowledge, and technological content—from advanced computer technology to agricultural production.

Today, the reality of full international economic interdependence is an inescapable fact. The figures are nothing less than astounding. U.S. exports grew from about $27.5 billion in 1965 to more than $700 billion in 1994. Imports during the same period registered similar growth, from about $22 billion to more than $800 bil-

[1] This chapter is based directly on my work with Stephen Yale-Loehr (Papademetriou & Yale-Loehr 1996)

lion (Council of Economic Advisors 1995:274-75). The total value of international economic transactions (imports plus exports) grew from a little more than 8 percent of the Gross Domestic Product [GDP] to more than 22 percent of GDP. By 1991, total international sales by U.S. multinationals (from exports, direct investments, or joint ventures) were responsible for an estimated $1.2 trillion, accounting for nearly 30 percent of corporate revenue (Ellis 1994:62-63). Even more telling, U.S.-owned firms now are competing with foreign-owned firms, not only abroad, but also in the United States. It has thus become as difficult and, in many respects, much less useful to distinguish "American" from "foreign" firms as it is to separate "domestic" from "foreign" markets for one's products.[2] Further, a firm's productivity and competitiveness depend increasingly on its products' knowledge content, on the innovativeness of its processes, on "first-to-market" corporate strategies and on the ability to develop and exploit global connections by what Moss Kanter (1995b:153) calls "managing the intersections" at the "crossroads of cultures." The constant need for specific expertise means that firms must be able to obtain some of the necessary talent easily from outside the United States—in effect, adopting a "just-in-time" approach to the composition of the work force. There is no argument among economists regarding the job-multiplying effects associated with the employment of such highly-endowed professionals; thus, U.S. business should have access to the best qualified individuals for key job openings. Hiring talented foreigners *at market wages* is also in the long-term interest of U.S. workers.

Yet, attracting immigrants with the higher-level skills that our economy needs now, and from which it can benefit well into the future, is an option that should be pursued as just one part of a broad competitiveness strategy. The U.S. simulta-

[2] The "American corporation" has become less and less "American" as companies move operations overseas and foreign capital pours into the United States. Between 1980 and 1992, U.S. overseas investments more than doubled, from $215 billion to $487 billion. At the same time, however, foreign investment in the United States more than quintupled, from $83 billion to $420 billion (U.S. Bureau of the Census 1994:808, 811).

neously must diligently pursue policies designed to enhance the education and training of U.S. workers while avoiding interfering too much—through undisciplined immigration policies or other initiatives—with the market's propensity to adjust to tighter supplies of highly-qualified workers. These are the parameters within which we should expect our corporate citizens to make decisions about whom they propose that we admit, through what process, and whether the person should be admitted permanently or temporarily—the former typically in response to longer-term and perhaps structural needs, the latter typically in response to shorter-term needs in areas of ongoing adjustments (Papademetriou & Lowell 1991). If the recruitment and admission principles and the accompanying mechanism are well thought out, they will have self-regulating parameters that will reduce access to immigrants in times of low demand for labor while expanding access in times of high demand.

Without a flexible and well-managed economic immigration selection mechanism, many of our most competitive firms with vast global operations may reconsider their investments in additional capacity *in the United States.* Firms whose products are primarily knowledge-based, such as software developers, can choose to expand anywhere the main intangible asset they need (knowledge workers) is in ample supply. Immigration policy—no less than policies to improve the quality of our human resources, maintain an excellent infrastructure, and provide a business-friendly regulatory environment—must thus support, rather than undermine, efforts to convince firms that they *can* remain and expand their operations in the United States and still be competitive in the global marketplace.

The Immigration Act of 1990 already has acknowledged the existence of a class of "global citizens" who are essential assets to successful economic entities in today's constantly changing world. It more than doubled the number of economic stream immigrants; it encouraged and simplified the immigration of exceptionally-qualified people; and it responded to the requirements of the global economy through extensive changes to the U.S. nonimmigrant system (Yale-Loehr 1991, Papademetriou & Yale-Loehr 1996). How-

ever, it passed without a focused discussion about the human capital characteristics that will be needed from the workers of the future. We must engage in that discussion now and think through more systematically the foundations—both in the permanent and temporary admissions systems—on which the economic immigration stream should rest in the context of global economic changes *and their implications for U.S. firms and U.S. workers.* The essential, and not yet answered, question is how to promote U.S. competitive interests by facilitating access to key foreign-born personnel without unnecessary procedures while simultaneously not undermining the broader social policy goal of advancing the interests of U.S. workers overall.

REFORMING THE SYSTEM: REVISED CRITERIA AND PRESELECTION

The selection of most economic stream immigrants and nonimmigrants must shift away from the shortage-based, case-by-case certification system of the past forty years. Nonimmigrants who are allowed to work (H, B2, D, O, P, E, F, J) should be admitted to the United States to:

- Fill a specific labor need, generally for a temporary period;
- Discharge our international obligations under a variety of trade, investment, and cultural exchange regimes;
- Facilitate international commerce and trade; or
- Enhance the cultural and artistic life of the United States.

To varying degrees, the current nonimmigrant visa categories already satisfy one or more of those requirements. In some instances, the present system also incorporates job and wage protection mechanisms that tend to focus on the unskilled and semiskilled workers who have dominated employment-based admissions throughout most of that system's life. In the future, however, the rationale—and appropriate selection procedures—for choosing among possible entrants should

focus squarely on their capacity for contributing to a technologically sophisticated and global economy.

Certain administrative and programmatic guidelines also are necessary to help the United States select economic nonimmigrants efficiently and should be part of any new immigration system. The selection process should be efficient, timely, fair, and transparent for all parties. Enforcement, including postentry enforcement, should become a credible deterrent against fraud and abuse. The selection system constantly should be reviewed and adjusted to make sure that it continues to serve the country's changing economic and labor market needs. (Thus, priority should be given to the collection and reporting of accurate data critical to monitoring and evaluating the impact of any new selection system.) Finally, the functions of the various federal agencies that, in one way or the other, play a direct or indirect role in the admissions process should be reconfigured.

Further, the current work-permitting nonimmigrant categories should be divided into two subsets: those for which substantial changes are proposed; and those that require fewer adjustments. The first subset focuses on the H visas —visas available to U.S. employers for positions for which U.S. workers are generally presumed to be unavailable. (See this volume's introduction for a discussion of the various H visas as well as, more generally, the entire "nonimmigrant" system.) The second subset (B2, D, E, F, J, O, P) incorporates visas for workers whose *primary* purpose should be generally other than to work within the United States with a U.S.-based employer (B2, D, E, F, J).

PRESELECTING (H) FOREIGN WORKERS

The H nonimmigrant visa category is the main temporary foreign worker category in the Immigration and Nationality Act [INA]. With some notable exceptions, the United States had for many decades prohibited the temporary employment of foreign workers. That ban was lifted in the 1952 Act, which authorized the Attorney General to admit temporary workers to "alleviate labor shortages." In FY 1994, 143,492 H nonimmigrant workers (plus an

additional 40,490 spouses and children) were admitted. The size and significance of the H category hence requires the careful con-sideration of appropriate models for selecting the foreign workers who receive that visa.

Currently, the U.S. selects some H workers on a case-by-case basis on a decades-old understanding of the U. S. economy and the role that foreign workers play in relieving labor shortages. Many European countries use similar case-by-case methods. That concept is strikingly at odds with today's competitive realities, where firms choose workers (U.S. or foreign) because of small differences in qualifications (both in quality and, especially, in the specificity of skills). Firms generally believe that such differences can, in turn, lead to substantial differences in their ability to compete without any loss in momentum.

There are other selection methods. For instance, one can select immigrants on the basis of certain analytically-derived "shortage" occupations (demand test); or one can select them on the basis of their ability to meet a set of skill and adaptability requirements (supply test).

Most of the discussion that follows has evolved primarily out of proposals for revamping the selection system for permanent immigrants and particularly the selection formula for what my colleague Stephen Yale-Loehr and I call the "second tier" economic or permanent immigrants (1996:144). Our proposed system would have three tiers:

First Tier/The Truly Outstanding. The top tier of our new economic immigrant visa system would be similar to the current Employment Based [EB-1] immigrant visa category for "priority workers." Foreign nationals with extraordinary ability enhance the economic strength of the United States and should be admitted with a minimum set of procedures.

Second Tier/Professionals Who Meet Certain Selection Criteria. Qualifying for the second tier would require a job offer; the worker considered should have at least three years' work

experience and the sponsoring employer would have to make certain attestations. Individuals also would need to qualify under a selection formula, outlined below, that awards value points for certain human capital attributes.

Third Tier/Investors. Investors enhance the economic well-being of the United States through their capital investments and should continue to be admitted, although under an amended set of requirements that focuses more directly on the visa's intent.

As this chapter focuses on nonimmigrant categories, there is no detailed discussion of the proposed changes in the permanent system—except for those for the second tier. That tier's threshold requirements and calculable point total for desirable traits also is the basis for selecting workers for the H nonimmigrant categories. The proper question to ask in this regard is how to devise a system that facilitates the selection of foreign workers best suited to contribute to the U.S. economy without harming U.S. worker interests.

U.S. INDIVIDUAL WORKER LABOR MARKET TESTS

The United States uses a variety of systems for screening foreign workers admitted for work. I discuss primarily two of these systems: labor certification (an individual worker test that emphasizes preentry screening) and attestation (a test that emphasizes postentry enforcement). Although the former is more stringent, both are intended to safeguard U.S. worker interests.

Preentry Tests: Labor Certification

One way to select foreign workers is to test individual applicants against a particular job opening at a particular place and point in time. Following the 1965 immigration amendments to the INA, granting an employment-based immigrant visa is prohibited unless the immigrant's prospective employer first obtains a certification from the Department of Labor [DOL] that there are no U.S. workers who are able, willing, qualified, and available

to perform the work and that the immigrant's admission will not adversely affect similarly-situated U.S. workers. The United States uses variants of this model for its H-2A and H-2B temporary labor certification systems.

Assessments of the certification system consistently have found that the system is excruciatingly complicated (Papademetriou & Yale-Loher 1996:104). The conclusions of a twenty-five year old assessment of the permanent labor certification system by David North (1971) still are applicable: labor certification had "absolutely no impact on the macro labor market" and affected the work force "only marginally" because it governed the admission of so few and because there were no controls over the worker after he or she arrived in the United States. Only about 59 percent of the labor certifications granted at the time were actually used, and about 45 percent of the labor certifications approved were issued simply to legalize foreign workers who were already in the United States (North 1971:iii). North concluded that, while the labor certification program was "an interesting (if limited) experiment in social engineering," an alternative approach was needed (North 1971:172).

The Prevailing Wage Issue. Then and now the most-often-heard technical critiques focus on determining an occupation's prevailing wage for certification purposes and on the effectiveness of testing the labor market for appropriate U.S. job applicants. Determining the prevailing wage is not easy. For labor certification purposes DOL uses the arithmetic mean wage, usually derived from small, nonrandom samples (U.S. DOL 1995a). Moreover, State Employment Security Administrations [SESAs] differ dramatically in the care with which they conduct their prevailing wage surveys. Some states use more sophisticated survey techniques and may allow for fine gradations within occupations (and as a result recognize more bases for wage differentials) than others. As a rule, the statistical validity of SESA surveys varies from totally invalid to valid with strong reservations.

The problem has grown more acute since 1990, when Congress imposed a prevailing wage requirement as part of the H-1B attestation process. Currently, the SESAs

receive more than 60,000 requests annually for prevailing wage determinations and must conduct more than 10,000 surveys annually, at a cost of nearly $20 million to DOL (U.S. DOL 1995a). In 1992, DOL created a prevailing wage advisory panel to review existing methods and procedures. The panel made twenty-nine recommendations for improving the determination of prevailing wages, including focusing on skill levels rather than years of experience to determine where an individual fits within an occupational range, using the median wage rather than the weighted arithmetic mean in certain wage surveys, and allowing employers to use fringe benefits in certain circumstances as part of the overall wage. Despite these recommendations, DOL made no significant changes.

Instead, DOL issued a long memorandum trying to clarify various prevailing wage issues (U.S. DOL 1995c), some of which serves only to aggravate the problems. For example, the new memo instructs SESAs to acknowledge just two skill levels for any particular occupation: entry and experienced (U.S. DOL 1995c). While this makes determinations easier, it does not accord with business reality, in which employers may set a variety of skill levels within an occupation depending on professional accomplishments, length of experience, responsibilities involved in the job, and other individual and contextual factors.[3] The new DOL memo causes additional problems by instructing SESAs to ignore distinctions between public and private and academic or nonacademic firms, although nonprofit entities typically pay less than private companies do, often in return for making the individual more competitive for future jobs.

The Job Description Issue. Most labor certification-type applications require the employer to post and/or advertise a job opening for a specified amount of time. Many resulting job descriptions are obviously designed to fit the foreign worker. Anyone skimming the classified ads in a large metropolitan newspaper quickly can distinguish a regular help wanted ad from

[3] For example, a computer software company may have five different levels of computer programmers and pay each level a different wage. For immigration purposes, however, SESAs are supposed to calculate just two prevailing wages: entry-level and experienced.

a labor certification ad: the former typically is short and to the point; the latter are much longer because they must track the exact language of the detailed job description filed by the employer on the labor certification application. Labor certification ads, moreover, instruct interested applicants to contact their local SESA, not the employer whose name cannot even be mentioned.

The process often pits clever employers and immigration lawyers against DOL's restrictive recruiting requirements. For example, if a newspaper ad is required, employers may try to place the ad on days when fewer people are likely to read the help wanted ads. Because all U.S. applicants must be considered, an employer intent on hiring a preselected foreign national seeks to minimize the number of U.S. applicants—just the opposite of normal recruiting practice.[4] Thousands of U.S. workers a year are nonetheless referred to advertised job openings, but few are hired. The complexity and increasing irrelevance of labor certification regulations thus regularly transform the certification process into a cat-and-mouse game. In the final analysis, SESA and DOL regulators can never be as familiar with an employer's business or industry as the employer, and they have many cases to decide with relatively few resources.

Thus, everyone is a loser in this process. The government loses, in that it is forced to play by and defend a process that is resource-intense and perverse in both execution and outcome and that offers ample grounds for cynicism among those who participate in and observe it. Many U.S. applicants see themselves as pawns in this process, and virtually all SESA and DOL officials acknowledge that the labor certification system does not protect U.S. work-

[4] Additional "protections are equally likely to fail. For example, the employer cannot reject U.S. applicants unless their resumes clearly show that they fail to meet the *minimum* requirements for the job. Even if the resume is ambiguous, the employer must nonetheless interview the applicant, either in person or by phone. Further, the employer must contact a qualified applicant promptly after referral by the local SESA or face possible denial of the labor certification application. Finally, employers can reject U.S. applicants only for "objective" job-related reasons, not for subjective criteria, such as apparent lack of motivation or a person's seeming disinterest in the job.

ers. The system is vulnerable to those who would "play" it; thus, some employers might use the system to bring in their relatives, while others might—and some do—pass on the costs of the certification process to their foreign-born employees through lower wages which, in turn, adversely affects the wages of U.S. workers. The current system, especially if it is applied more stringently,[5] as some advocate, arguably could hamper the efforts of some U.S. firms to become fully competitive in the global economy and might even harm our country's long-term economic interests *without simultaneously offering substantial additional benefits to U.S. workers*. This well may be the most telling critique of labor certification and the most compelling argument for its replacement.

Postentry Tests:

Attestation

Aware of many labor certification shortcomings, the U.S. Congress created a new method for protecting some U.S. workers while facilitating employer access to certain nonimmigrant foreign workers: attestation. Attestation is a simpler mechanism that reduces up-front barriers to the entry of needed foreign workers, but still attempts to protect U.S. workers through postentry enforcement of terms and conditions of employment. The first attestation system was enacted as part of the Immigration Nursing Relief Act of 1989, which expired in 1995. Under this system, a health care facility had to attest to six criteria before it could hire an H-1A foreign registered nurse. Three more attestation systems for non-immigrants were created in the Immigration Act of 1990:

[5] Proponents of the *status quo* claim that the current system has some advantages. The very cumbersomeness of the process, for instance, probably discourages frivolous applications. However, frivolous applications should be weeded out through clear rules and effective, targeted enforcement, not by making the whole system so bureaucratic that it deters both meritorious and frivolous applications. DOL recently has begun a reengineering effort to streamline procedures, save money, improve effectiveness, and serve its customers better (U.S. DOL 1995b).

one for crewmembers in the D visa category; another for foreign students in the F visa category; and a third for specialty occupation workers in the H-1B category.[6]

Attestation, at least as presently practiced, also has a number of shortcomings. Some of these are similar to those in the labor certification process. For example, determining the appropriate prevailing wage can be quite difficult for both the employer and DOL. Further, some documentation requirements of an attestation are quite burdensome. For example, an H-1B employer's documentation must include information about all other employees in the same job in question, from the date the H-1B labor condition application was filed throughout the period of employment. An employer also must specify the basis on by which he or she calculated the actual H-1B wage. Attestations also have the potential for becoming pawns in instances of troubled labor relations if worker representatives choose to interfere systematically with management's access to foreign workers by frivolously challenging attestations.

Nonetheless, attestation has several positive attributes. If conceived and implemented well, attestation can balance the need to safeguard and advance the interests of U.S. workers while offering most employers timely and predictable access to needed foreign workers. Attestation also meets an important *public process test* by giving potentially affected parties an opportunity to know about and challenge the matters to which an employer attests. A properly conceived and executed postentry test can be among the mechanisms most responsive to changing conditions in labor markets, while requiring the least amount of hands-on engagement by the U.S. government in an area where both data and procedures are the weakest. It can also be an inducement to cooperative labor relations in instances where workers' representatives and management work together to obtain the best worker available for a job opening.

[6] The H-1A attestation process arguably was the most complex and intrusive of the four systems because it required an employer to take "significant steps" to recruit and retain U.S. nurses. None of the others places an affirmative obligation on employers to try to reduce their use of foreign workers.

Labor Market Information Model

An alternative way to select foreign workers for job needs/openings is to use generalized labor market information [LMI]. Unlike the individual worker evaluation model, this method focuses on making judgments about labor shortage and surplus occupations on the basis of general labor market information gathered primarily from national level data. Employers would be allowed to bring in foreign workers freely for occupations that are determined to have a labor shortage. In theory, an LMI method has several advantages over labor certification, particularly in terms of costs and responsiveness.

However, the disadvantages of an LMI approach strongly outweigh its potential advantages. First, the use of LMI to categorize occupations appears more "scientific" and "rigorous" than it really is. First, it creates an illusion of objectivity while, in fact, it relies to a very substantial degree on subjective judgments. Second, the data on which a LMI approach would rely were developed for other purposes and do not measure the precise concepts needed. Third, most occupational shortages are relatively brief in duration and all shortages are dynamic; some of the data used to identify shortages simply may be picking up indications that the market is adjusting. Fourth, even if the U.S. government could identify occupational shortages appropriately and in a timely manner, it could not ensure the timely admission of immigrants with those skills. Finally, the fundamental weakness of a LMI approach is that national data tend to "average out" and, thus, routinely mask often-substantial regional and local variations.[7]

[7] In practical terms, the geographic concentration of immigrants probably means that only a few local area lists of shortages would be used frequently. Legally, however, it might be necessary to develop comparable lists for all localities. Moreover, such a nationwide list would be quickly outdated, resource-intensive to update, and still would not prevent employers from claiming that, despite the LMI evidence, they could not obtain a worker for a specific need. Such a claim would return the entire process to its case-by-case determination roots.

Point System Model

A point system model of economic stream immigration, at least as practiced by Canada and Australia—the other two major "countries of immigration"—differs from both the individual worker job evaluation model and the labor market information concept. Unlike the former, a point system does not focus on matching a specific immigrant with a specific job offer in a case-by-case process. Unlike the latter, a point system neither directs, nor necessarily limits, immigrants to working in predetermined labor shortage occupations. Instead, the point system evaluates and selects immigrants based on certain human capital characteristics deemed to advance the host country's interests.

A point system theoretically has several advantages over either an individual-worker job evaluation or a LMI model. A point system can inspire confidence as a policy instrument that applies universal and ostensibly objective selection criteria; hence, it is less susceptible to criticisms associated with the case-by-case system's gamesmanship between employers and bureaucrats. Further, a point system's appearance of impartiality may discourage most of those who otherwise might have been apt to challenge it, while its technical complexity and apparent responsiveness to long-term labor market needs is reassuring to many who worry about possibly adverse effects on domestic workers. Finally, depending on the attributes the point system emphasizes, the model may reassure members of the receiving society that economic stream immigrants are selected on the basis of criteria that place high priority on the country's global competitiveness. This makes the system more politically defensible than any of the alternatives discussed above.

Can a point system work in the United States? The answer is a qualified "yes, *but only if the concept is adapted to the idiosyncrasies of the U.S. economy, philosophy, and labor market realities.*" On the one hand, despite inevitable variations that stem from location and history, the origins, scale, and composition of most immigration to Canada and Australia has not looked all that different from ours. On the other hand, a point system would require special discipline to be effective in the United States.

Our system of government is different enough from the Canadian or Australian ones to affect a key feature of a point system, its flexibility. The appeal of a point system is that it can respond quickly to shifting priorities and the Canadian and Australian parliamentary systems are well-suited to make these changes. At the minister's direction, the immigration ministry professionals come up with a plan to adjust the point categories and their relative weights, and Cabinet approval can be obtained quickly. In many instances, the changes can be accomplished administratively, under broad grants of authority delegated by the relevant statute. By contrast, the U.S. system is deliberately designed to work more slowly. On immigration, most of the input comes from the legislative (and even judicial) branches, as well as from affected constituencies. Under a point system, Congress would have to be willing to delegate many of the details to the executive branch, and the executive branch would have to take on significant responsibility for managing such a system.[8]

PRESELECTION AND H NONIMMIGRANTS

Despite these cautionary notes, the advantages of adopting a point-like system in the United States are clear and compelling in the case of H nonimmigrant workers. Such a system would shift the focus from an almost exclusive emphasis on shortages to enhancing the United States economic posture. Properly conceived and implemented, a point-like system would allow the U.S. government to do what it can be fairly good at, particularly when it does so in cooperation with the private sector, rather than forcing it to do what it is least good at, i.e., performing burdensome and ultimately unsatisfactory case-by-case and similar preentry evaluations.

[8] A point-like system places a great burden on the immigration agency. Done properly, it requires the creation of a data collection, analysis, and evaluation mechanism that allows policymakers to determine whether the chosen categories are the right measures of economic growth and personal success and whether the categories are weighted properly. Further, the immigration agency would have to develop a more appropriate administrative infrastructure and a more open and cooperative institutional culture.

Employer Sponsors and Flexible Limits. Under our proposed reforms, employers would continue to make all selection decisions,[9] but they would have to select from a pool of individuals who can pass a threshold of requirements, including a points test.

Employers also would be required to attest to certain recruitment, wage, and employment conditions. Numerical limitations would be imposed, as, from a political perspective, Congress and the American people would not tolerate even the theoretical possibility of open-ended immigration however robust the safeguards or well-administered the system. For that reason, Congress should set initial caps for the H-1 and H-2B categories but allow a year's ceiling to be based on the previous year's actual usage plus an increment of, say, 10 percent. This would offer greater flexibility than a hard cap, which would require legislation to amend. This method would also allow employers adequate access to foreign workers if the economy suddenly improves or if they encounter a true shortage of talented U.S. workers in an emerging growth area and need more foreign workers with highly-specific skills.

Selection Criteria for a Point Test. In addition to employer sponsorship and attestations, there should be prior requirements that employers and prospective immigrants must meet if they wish to enter the immigration sweepstakes. Employers must select from a pool of possible non-immigrant workers who must have personal characteristics that are essential to making a sustained and substantial contribution to the United States:

- An *educational background* that has instilled both specific knowledge or technical skills *and* a facility for abstract thinking;

[9] Not all companies need to be eligible to prequalify for the second tier attestation requirement, even if they have excellent recruitment, compensation, and employment policies. For example, Congress might consider withholding the prequalification benefit from firms: (1) that file more than a certain number of immigrant visa petitions per years; (2) whose foreign national workforce exceeds a certain percentage of the total workforce in the company; or (3) that have been found in violation of any immigration law within a specified period.

- An *age* that permits one to make a substantial contribution to the economy immediately;

- The *language* ability and communications skills necessary to interact effectively with colleagues and customers; and

- A demonstrated *commitment to improving* one's own human capital endowments.

Numerical weights can be assigned for each of these preselection criteria, with different thresholds set for different visa classes—although it makes little sense to legislate fixed weights or criteria.[10] Congress moves too slowly to enact detailed changes on immigration and, just as we want the economic immigrants we choose to be able to adapt, so too we need flexibility in our selection system. Hence, immigration officials should be given authority to change both the criteria for preselection and the number of points needed to qualify as economic conditions change. Flexibility is essential for the success of a modern immigration system and Congress' need to stay engaged can be discharged by requiring that proposed changes be vetted in advance with the two subcommittees charged with oversight responsibilities. If actual usage increases by the maximum percentage one year, to help control the growth in foreign workers in the following year, administrators could investigate the causes for such an increase and might choose to raise the pass mark needed to qualify for a given nonimmigrant visa category.

Attestation requirements. Employers would have to attest that they would comply with the four conditions that they do now for H-1B purposes, as well as a new recruitment condition.[11] First, the employer still would have to offer the higher

[10] It is up to Congress to engage in a dialogue about the number of points for each factor and the minimum number of qualifying points. Keep in mind that no selection system can accommodate all situations; hence, prospective employers of foreign nationals in certain occupations who are just one or two points shy of the pass mark might be permitted to submit evidence why the individuals nevertheless should be allowed entry. Alternatively, INS might have access to a variation of the current "national interest waiver" test for exceptional cases.

[11] Employers would have two ways to satisfy the proposed attestation requirements: prequalification or case-by-case.

of either (1) the actual wage the employer pays to other individuals similarly employed with similar qualifications or (2) the "prevailing wage" for that position. The current reliance on SESA prevailing wage determinations should be abandoned in favor of developing prevailing wage and total compensation package information from reliable industry-specific sources.[12] Second, employers would have to attest that there is no strike or lockout at the place of employment. Third, employers would have to attest that they have given their employees notice of the filing of the attestation. Fourth, employers would have to attest that the process through which the foreign worker was selected is the employer's and the industry's customary way of making hiring decisions for this kind of position.[13] Significantly, contracting with "job shops" that supply a predominantly foreign work force would not be considered a customary recruitment practice.

International Commitments. These recommendations for the H-1 category are fundamentally consistent with U.S. international commitments in this area. As part of the General Agreement on Trade in Services [GATS], the United States agreed to freeze the essence of the current H-1B program but created room for three possible changes in the future: (1) reducing the maximum length of the visa from six to three years; (2) instituting a provision that would prohibit employers from laying off U.S. workers and then using H-1B workers in the same occupation; and (3) requiring employers to take significant steps to recruit and retain U.S. workers. These proposals are consistent with the first two of these provisions. Further, the proposed recruitment attestation require-

[12] Currently, H-1B employers also must attest that the working conditions for an H-1B worker will not adversely affect the working conditions of other workers similarly employed. This requirement should be deleted as most of its provisions would be covered under the "total compensation package" concept and because it has not proven to be a meaningful protection.

[13] To understand the industries they regulate better, we propose that INS and DOL, as a matter of course, include organized discussions with panels of human resources personnel from various industries in *all* of their training sessions and meetings on customary hiring regulations.

ment is consistent with the spirit of the third element.[14]

Dual Track H-1. Historically and practically we know that permanent immigrants in the economic stream typically adjust in a manner that turns the holders of many temporary visas into "*pre*immigrants." In many instances, employers hire them for specific needs, but also to determine whether they are suitable for permanent employment. This occurs primarily in the current H-1B nonimmigrant visa category. We propose that, at any time after the first year and before the three-year period ends, an H-1 employee could petition for an immigrant visa, putting employers on notice that they will not be able to employ a foreign worker for long periods unless the worker can ultimately qualify for such a visa. Such prospective immigrants should be assigned their own nonimmigrant visa [NIV] category and be selected from a pool of individuals with characteristics that will enhance their long-term contributions to the economic strength of the United States, facilitate international business and trade, and generally promote U.S. interests and priorities.

H-2B Visa Category. The H-2B visa would be restructured along the lines of the H-1 and should be refashioned to be more than just a catchall category, but rather a category that focuses on truly temporary jobs. Following thorough assessment, subcategoriess of the current H-2B category that are primarily cultural in nature, such as camp counselors, should be incorporated into a revised and appropriately reconfigured J category, etc. It is here that the *second strand* of the H-1 workers—those who employment would be truly *temporary*—would be expected gradually to find a home. In reconfiguring this category, a variation of the double-temporary standard now in existence (i.e.,

[14] These modifications theoretically could conflict with GATS. A computer programmer with a bachelor's degree who speaks only a little English currently can obtain an H-1B visa easily; however, under the proposed selection criteria he/she might not. If not, his or her country could claim nationality discrimination. The proposed criteria, however, filter an applicant's *personal* characteristics and do not violate the equal treatment principles of our multilateral obligations.

both the foreign worker and the job are temporary) should be maintained, as should be the maximum number of two one-year renewals.

By developing incentives and disincentives for the long-term employment of many H-2B workers, the proposition can be tested that there are some occupations in which some of the labor demand might be satisfied by training U.S. workers. This would be particularly relevant and appropriate for many low-skilled occupations—ranging from household workers to specialty chefs—where a person's personal characteristics, such as language, ethnicity, familiarity with an "ethnic" cuisine, etc., is presumably valued by the employer. It may be found that, in most cases, one could no longer show that "shortages" exist in these occupations.

H-2A Visa Category. This visa category allows employers temporarily to employ agricultural workers following a test of the labor market and strictly regulated attempts to hire a U.S. worker. Serious thought should be given to replacing this category with a program that focuses on enhancing employment opportunities for U.S. agricultural workers, while acknowledging the unique nature of that labor market, its binational (primarily Mexican) composition, and the historical (and future) reliance of that sector on a foreign workforce.

CHANGES ON OTHER WORKING VISAS

The discussion below proposes modest changes to several other NIV categories to make each of these visas comport with the priorities outlined above. Unlike the H visa, where the primary purpose is U.S.-based employment, other nonimmigrant working visas have other primary purposes. Failure to mention an existing category means that no changes are proposed.

B Visa Category. No changes are necessary in the B-2 tourist visa category. This category facilitates international tourism. In 1994, more than 16 million foreign tourists visited the United States, generating an estimated $60 billion in revenues (U.S. Bureau of the Census 1994:264). The B-1 temporary business category also is gen-

erally fine in concept, as it facilitates international commerce and trade. However, concerns about certain types of abuses—improper use of the B-1 in lieu of the H-1B visa[15]—must be taken seriously and addressed through clearer regulations and more active enforcement, not by severely restricting or eliminating the category.

Extreme care in changing the B-1 visa is particularly necessary because of the reciprocal nature of international trade. If the United States eliminates or severely curtails access to this category, other countries may retaliate and impose similar bans on U.S. workers wishing to enter and conduct similar activities in those other countries. Our trade commitments have bound this use of the B-1. For this reason, radical changes to this visa would require difficult renegotiations and, if undertaken unilaterally, could lead to trade-related sanctions against the United States.

D Visa Category. It is unclear whether this category for foreign crewmen needs any changes. Very few attestations for longshore workers under the D category have been filed since the attestation requirement took effect after the 1990 Act. As a result, DOL and the Department of State [DOS] should prepare a report on the implementation of the D attestation process that should contain a cost/benefit analysis of the current regulations and assess whether such an interventionist regulatory regime is necessary—especially considering the small number of people it affects. One possible change might be to negotiate more balanced reciprocal arrangements with key shipping countries, rather than continuing to impose burdensome requirements on a wide universe of countries.

E Visa Category. The category of treaty-traders and investors is essential to international commerce and trade and, insofar as we have institutionalized that visa's

[15] This particular use of the B-1 visa should be reconceptualized and better formulated to (1) accommodate the constantly changing nature of international business and (2) provide for the sound discretion of properly trained visa-issuing officials in deciding whether the proposed activity is consonant with the visa's intent.

regulations in our international commitments, our ability to change the E visa is severely limited. Pending proposals for new regulations by INS and DOS are nonetheless worth testing. Among them are heightened scrutiny of E visa employees with "specialized" qualifications who are "essential" to the company. More specific issues, such as whether or not the employer can find qualified U.S. workers, and issues regarding E visa interchanges with the L visa category for certain multinational executives, managers, and employees possessing specialized knowledge, might be handled better in negotiations with other countries to achieve full reciprocity. As with the D visa, multilateral regulatory changes in many of these visa categories generally are preferable to unilateral attempts at closer regulation.

F Visa Category. Foreign students should continue to be allowed to work off-campus if the work is related to their academic studies. INS also should consider extending practical training options for foreign students in F-1 and J-1 status so that employers still would be able to hire qualified foreign nationals on a short-term basis. However, there is at least the potential for adverse effects on U.S. workers from the unregulated employment of F-1 students.[16] For that reason, we propose requiring employers of F-1 students to file a wage attestation similar to the one proposed for second tier immigrants and several "H" nonimmigrants. Work authorization for "economic hardship" also should be maintained, although INS should tighten its oversight of such grants.[17]

---

[16] Any problem with "oversupply" of foreign nationals in graduate science and engineering programs should be dealt with by the government and the private sector encouraging more Americans to enter those fields (1) by getting young people excited about sciences when they are in elementary and secondary schools and (2) by making more public funds available for fellowships and traineeships so that more Americans can pursue advanced studies.

[16] A report by Casals and Associates (1994) of the off-campus work program found that, while on average only about 10 to 20 percent of F-1 foreign students obtain work authorization based on economic necessity, almost 75 percent of F-1 foreign students at one college worked off-campus under the economic necessity exemption. Such a statistic raises fundamental issues about possible abuse of the exemption and suggests that the "primary purpose" for which some of these students came to the U.S. may have been employment, rather than education.

The pilot off-campus work program should be eliminated because it allows foreign students to engage in general labor unrelated to any verifiable unmet labor need. The F-1 attestation process has not worked; very few employers use it and, in many instances, schools can issue work authorization for their students through other available means. This recommendation is consistent with the recommendations of DOL and INS as expressed in their 1994 joint report to Congress evaluating the program.

J Visa Category. This visa for various types of exchange visitors should be retained because of the very nature of international cultural exchange, education, and training. Other nonimmigrant visa categories that contain a cultural component, such as the H-2B and Q visa categories, should, however, be incorporated into a revised, expanded, and more stringently administered J category. In keeping with the purposes of the J visa, work authorization should be truly incidental to the primary cultural exchange, educational, or training purposes. To serve U.S. worker interests better, any work authorization for J-1 visitors should require compensation at full market rates. However, if J-1 sponsors pay part of the J-1's wage, this should be factored into any determination of the total compensation package.

One of the J-1 visa programs—the *au pair* program—does not comport with the spirit and aims of the J visa category. Despite the U.S. Information Agency's [USIA] recent attempts to control abuses in this program and make it more culturally focused, most U.S. families who use the program view it *first* as a work program and *only then* as cultural exchange. This is one of the main reasons why USIA has been stating publicly for many years that it does not feel comfortable administering the *au pair* program. A radical restructuring of the regulations is required so that the *au pair* program serves the same purpose it does in many other countries: providing a mutually valuable cultural exchange for *au pairs* and the families with whom they live.

Further, the administration of the revised and expanded J program should be transferred from USIA to INS, the agency with the broadest mandate and expertise in this area. INS already has experience admin-

istering visa applications of this type, such as in the current H-2B and Q categories. It could administer J programs without significant additional expenditures, especially since much of the current J program is run by responsible officers at sponsoring organizations. The transfer should be at least revenue-neutral and, in all likelihood, could save a modest amount of money. Additionally, INS would have the enforcement oversight capability now lacking in the USIA-administered program. Thus, the recommended transfer also would move the U.S. toward *the consolidation of all functions in the immigration agency*, an objective that undergirds the comprehensive rethinking of the country's immigration function that the Papademetriou and Yale-Loehr study (1996) envisions.

REORGANIZATION OF IMMIGRATION MANAGEMENT

At present, immigration functions are scattered not only between INS and DOL, but also among the DOS's Office of Population, Refugees and Migration, the Department of Health and Human Services' Office of Refugee Resettlement, the Department of Education, and USIA. Almost all of these functions could be performed more efficiently and economically by a larger, reengineered, and more independent INS. Such a change is essential to a revamped way of managing our immigration system.

The immigration function at the federal level should be reorganized as follows.

The Immigration and Naturalization Service. Congress should give INS an independent status that accords with its size and responsibilities, consolidating most immigration functions in the agency. To make this proposal work effectively, INS needs to develop a specialized corps of adjudicators, to be posted overseas, whose sole responsibility would be to handle economic stream immigrant and nonimmigrant visa applications. This corps of INS visa adjudicators gradually would absorb most of the functions now performed by the DOS's Bureau of Consular Affairs. Having this specialized corps also would help speed adjudication of all petitions at INS regional service centers, which is critical to avoid delays.

The Department of Labor. The labor certification and related functions now performed by DOL's Employment and Training Administration [ETA] would no longer exist. Its enforcement mission should be upgraded and the Secretary of Labor should continue to play a role in the administration's deliberations on immigration policy.

The Department of State. A streamlined Consular Affairs Bureau would continue to perform its core diplomatic-related functions, such as passport issuances and citizen services. The Bureau of Population, Refugees and Migration [PRM] would continue to discharge its specialized mandate, but its refugee resettlement functions, together with the resettlement functions now residing within the Department of Health and Human Services, should be folded into INS.

Such changes are truly daunting. They require careful thinking as to allocation of specific responsibilities, personnel, and resources. They also require comparable changes in the legislative function—a function that now is divided among too many congressional committees and subcommittees. Therefore, an independent study group, which should include representatives from affected parties, should be convened to examine and report on this difficult reorganization issue.

Data Collection and Evaluation. Regardless of any changes in the administration of immigration, there must be a commitment to better data collection and critical program evaluation. Few weaknesses of our current system are more frustrating to analysts, policymakers, and the public than the various immigration agencies' inability to answer many questions regarding the characteristics, behavior, and needs of their client base with any degree of confidence or reliability. It is inconceivable that a country for which immigration constitutes such an extraordinary component of economic, social, cultural, and political change would continue to tolerate legislating in the dark. Congress must make it clear *in legislation* that it values such information and analysis, that it expects the relevant agencies to attain these goals, and that it will monitor their progress.

Compliance Enforcement. A credible enforcement regime is absolutely necessary to deter fraud and deny immigration ben-

efits to those who do not qualify. To put its limited resources to best use, DOL should be given explicit authority to target "high-risk" employers, i.e., those with high fraud and severe exploitation practices. One way to focus investigations would be to check an employer's W-2 statements, submitted with H-1 attestations, against the required wage on the attestation form. Permitting anonymous complaints also would make sure that employers do not retaliate against whistleblowers. To promote efficiency and pay for compliance efforts, INS should develop a fee structure that reflects the agency's true costs both for doing a much better job *and for supporting DOL's enforcement apparatus*. At present, INS charges only minimal fees for helping U.S. businesses to obtain foreign workers, and DOL charges none at all. Congress should establish a funding mechanism that uses dedicated parts of the application fees for audits, investigations, and enforcement.[18]

Better Cooperation between Business and Government. An honest and open dialogue between business and government on immigration-related labor regulations is badly needed. DOL and INS should focus their regulations and enforcement sharply on targeting egregious conduct, allowing the majority of compliant businesses to make personnel decisions without having to contend with disruptive and, ultimately counterproductive, regulations. Business must, in return, help DOL and INS to obtain the appropriate legislative and regulatory tools for carrying out a renewed enforcement agenda.

For their part, the immigration agencies must seek the assistance of business in better understanding each industry's customary hiring practices, in identifying business practices that are out of the ordinary and may thus require additional scrutiny, and in devising ways to perform their responsibilities more effectively. Such

[18] However, INS should not try to make employers pay more than their fair share by creating numerous "indirect expenses" that the agency claims support adjudication of economic stream petitions. Criticism already exists concerning the current examinations fee account. Congress also should assist INS in making sure that fees from economic stream petitions go immediately to the examinations division at INS—without going through the normally lengthy budget planning or preprogramming procedures.

negotiated rule-making would accord with President Clinton's recent guidelines which called on "all regulators to . . . create grass-roots partnerships with the people who are subject to [their] regulations and to negotiate rather than dictate wherever possible" (OFR 1995).

The Problem with Job Shops. One way to start a business-government dialogue might be by focusing on the implications of recent corporate trends toward flexible staffing, particularly in high-technology sectors. In the name of efficiency, many corporations are moving away from maintaining large, permanent workforces and toward acquiring the services of technically-skilled workers *as and when needed*. It is now quite obvious that a large share of the most egregious violations of both letter and spirit of regulations governing temporary work-related admissions is committed by labor contractors, sometimes called "job shops," who offer flexibility to employers by recruiting and importing foreign workers. Job shops sometimes undercut prevailing wages, create oppressive employment contract terms, and refuse to invest in recruiting and training U.S. workers. Industry must recognize its responsibility to work with government to develop ways to curb such predatory practices, while DOL and INS must acknowledge reality and the benefits that flexible staffing provides.

Protections for U.S. Workers. Any programmatic revisions must minimize employer incentive and ability to exploit foreign workers by paying them less than comparably situated U.S. workers. Therefore, a number of protections must be built into the system that ensure fairness for foreign workers and a level playing field for U.S. workers. Employers should have to attest that they are paying foreign workers prevailing wages that *include* the value of all the benefits received by their U.S. workers (bonuses, health insurance, vacation, etc.). In addition to strengthening wage attestation requirements, we propose limiting the stay of temporary workers to three years, rather than the six years that are permitted under the present system, and strengthening their ability to bargain with employers by allowing them to change jobs after the first year if they are offered higher wages by another employer.

CONCLUSIONS

Although the current system's basic architecture is fundamentally sound, policy analysts and others have come to realize that certain components of the immigration system may no longer serve broader U.S. interests well—or, for that matter, the interests of many of those who participate in it. Specifically, reform must emphasize: (1) the right mix of incentives and disincentives for businesses to play by the rules yet succeed in international competition; (2) a more realistic, and ultimately more effective, understanding of what constitutes U.S. worker "protection" in the context of immigration and how best to advance it; (3) a new habit of cooperation between regulators and the regulated that could serve as a "partnership" model for other contentious policy areas; and (4) a new resolve to identify, isolate, and punish corporate citizens who habitually violate U.S. immigration laws.

The proposals made here would help to limit entry of all but the most talented—or truly needed—foreign workers. The threshold for the points test and related requirements virtually would eliminate the entry of low-skilled immigrants and temporary workers who are most likely to compete with qualified U.S. workers for entry-level jobs. More stringent requirements also should be considered for making sure that temporary workers who come in under certain parts of the H visa actually leave the country when their visas expire; such workers should also be denied readmission for at least a year. Further, employers should be required to recruit according to industry standards, something they are not now required to do for temporary workers; in particular, contracting with "job shops" that supply a predominantly foreign work force should not be considered a "customary recruitment practice" for purposes of wage attestation. Taken together, these requirements would create very significant new protections for U.S. workers.

Ultimately, the proposed scheme should be seen as a framework for a more thoughtful and forward-looking approach to selecting permanent and nonpermanent economic stream immigrants. Although some criteria for guiding selection—and priorities and numerical values for them—are suggested here, the more important

objective is to generate a dialogue about a more appropriate way of looking at our country's needs and priorities for the future and the place that economic stream immigration should play in promoting those interests. As these proposals become vetted, specific details may require reconsideration. The end result of such a dialogue should be a more transparent and robust selection system that is flexible, has adequate self-regulating and enforcement features, is consistent with what our economy "values" and rewards, and is thus fully consonant with our country's long-term interests.

SOME THOUGHTS ON NONIMMIGRANT STUDENT AND WORKER PROGRAMS

DAVID S. NORTH

Background

The Commission requested comments on the nation's nonimmigrant policies regarding students and temporary workers. For the purposes of this essay I focus attention on the following classes of nonimmigrants: F, H, J, L, and, to some extent, M. These are, respectively, the classes for: academic students (F), most temporary workers (the various H subclasses),[1] exchange visitors (the Js, which includes people doing many things, including studying and working), intracompany transferees (L), and the small class of vocational students (M).[2]

To complicate matters, "temporary" is not very temporary in many of these programs; for example, a foreign worker with an H visa can use it to work in the U.S. for as many as six years. Further, many nonimmigrants move through two or more of the nonimmigrant visa categories noted above while in the U.S., providing opportunities to spin out nonimmigrant status to as much as a dozen years. A final complication: a not insignificant fraction of those admitted to the U.S. as nonimmigrants adjust their status to that of permanent resident alien [PRA] or immigrants, but they do not necessarily do so from the nonimmigrant status that brought them to the U.S. in the first place.

[1] Excluded from this essay are the O, P, Q and R classes. These are new, relatively small, and quite specialized, dealing as they do with, among others, entertainers, the more prominent athletes, and people in religious occupations. The total number of admissions in these classes came to 34,443 in FY 1993, compared with 171,829 admissions in all the H subclasses for the same year. Similarly excluded for the same reasons are the relatively new class of Free Trade Agreement nonimmigrants.

[2] For a comprehensive, recent analysis of the labor market roles of all the nonimmigrant programs, see: Leibowitz 1994.

Before discussing policy matters it may be helpful to summarize the numbers involved in these programs, the over-lapping natures of the programs, and the agencies managing them.

The Numbers: The Big Picture. Exhibit 1 presents two sets of numbers over the last ten years, showing admissions in the four broad classes of interest and adjustments from these statuses to that of PRA. (In the exhibit, as in many of the data sets of the Immigration and Naturalization Service [INS], the rela-tively tiny M program is merged into the much larger F program.)

At first glance at the exhibit reveals two things: (1) most numbers have grown over time; and (2) the number of adjust-ments is a small fraction of the admis-sions. Both of these concepts are correct, but the nuances are interesting as well.[3]

A closer look at the table reveals that adjustments for Hs, Js, and Ls soared in 1992; this was the first year that the 1990 Immigration Act was in full effect, and it granted adjustments to people in the backlogs for the employment-related immigration visas. Similarly, the num-bers of Fs adjusting in 1993 peaked as a result of the post-Tiananmen Square Chinese Students Act, which permitted such students to secure PRA status.

The Numbers in More Detail. While **Exhibit 1** shows the long-term trends in these programs generally, it lumps several subcategories together. These were the FY 1993 admissions in each of the subclasses of interest:

[3] Admissions figures are for an event—someone passing through a port of entry—while the adjustment data count the number of people moving from one immigration category to another. A single nonimmigrant can record several admissions in a given year or only one for a long-term stay in the U.S.; in the classes of interest, the norm is for several admissions for every individual granted a nonimmigrant visa. Adjustments, however, except for very unusual circumstances, are once-in-a-lifetime events. Hence the admissions and adjustment numbers are not comparable.

Exhibit 1.
Admissions of Selected Classes of Nonimmigrants and Adjustments to PRA from those Classes
(FYs 1985-1994—Numbers Rounded to Hundreds)

Fiscal Year	Admissions of Classes of Nonimmigrants				Adjustments from those Classes to PRA Status			
	F & M	H	J	L	F & M	H	J	L
1985	315,500	87,000	141,800	106,900	22,600	8,000	2,100	6,300
1986	288,400	99,100	163,000	108,000	21,000	9,200	2,000	6,200
1987	288,600	113,500	183,000	108,800	19,600	9,100	1,900	5,400
1988	337,900	133,100	202,900	101,700	20,400	10,100	2,100	5,200
1989	362,800	162,500	214,600	100,700	21,900	11,000	2,800	3,900
1990	355,200	168,300	214,600	102,600	25,100	14,600	2,800	3,900
1991	*366,100	195,200	224,200	112,900	20,900	14,900	2,600	2,900
1992	*393,000	203,100	231,900	120,800	23,600	34,700	6,200	10,900
1993	*394,800	205,100	240,500	132,400	37,900	38,900	10,300	9,400
1994	427,700	260,100	259,200	154,200	29,600	30,300	7,300	8,600

Visa Classes: F = Academic students and
M = Vocational students
The former class outnumbers the latter by about 60-1 and INS merges the two classes in some of its statistics.
H = Several classes of temporary workers, some highly skilled, some not.
J = Exchange visitors, usually professionals.
L = Intracompany transferees are managers and professionals previously employed overseas by multinational firms.

Note: All statistics above include accompanying family members.

Source: Most data are taken from *Statistical Yearbook of the Immigration and Naturalization Service*; admissions data from Table 39 (1993) and predecessor tables and adjustment data from Table 10 (1993) and its predecessors. All 1994 data and the totals with asterisks (corrected data on F and M admissions) were provided by the INS Statistics Division by telephone and fax.

Admissions	Classes of interest
257,430	F-1 academic students
33,379	F-2 their spouses/children
6,437	H-1A nurses (category terminated 9/30/95)
93,069	H-1B specialty occupations (usually professionals)
16,257	H-2A farm workers
15,038	H-2B other blue collar workers (mostly)
3,135	H-3 industrial trainees
37,893	H-4 the spouses/children of H aliens
197,545	J-1 exchange visitors
42,911	J-2 their spouses/children
82,781	L-1 intracompany transferees
49,642	L-2 their spouses/children
4,382	M-1 vocational students
557	M-2 their spouses/children
676,074	Subtotal, primary beneficiaries
164,382	Subtotal, their spouses/children
840,456	**Total FY 1993 admissions in these classes**

Clearly people in some of these classes bring along more family members than others; presumably this relates to such factors as age of the prime beneficiary (one acquires more family members the further one is beyond one's twentieth birthday), expected length of stay in the U.S., and level of prosperity. (For example, F students are young, and H-2A farm workers, who do not usually bring family members to the U.S. when cutting sugar cane or harvesting apples, are nonprosperous.)

The ratio of dependents to principals, as a result of such factors, is quite different for the five visa classes. The ratios among the nonimmigrant admissions were as follows in 1993:

Dependents per Prime beneficiary	Nonimmigrant Class
.13	F
.28	H
.22	J
.60	L
.13	M
.24	all five classes

Overlapping Classes. It is useful to note the overlapping nature of these five visa classes. With the exception of the intracompany transferees (L), none of the full visa classes consists of only workers, and none consists only of students who do not work in the economy. A hierarchy, from full-time workers towards full-time students, looks like this:

Work only	L-1 intracompany transferees
	H-1A nurses (category terminated 9/30/95)
	H-1B specialty occupations
	H-2A farm workers
	H-2B other blue collar workers (mostly)
An uneven mix of work & study	J-1 exchange visitors
	H-3 industrial trainees
Study + some part-time & vacation work[4]	F-1 university students
	M-1 vocational students

In addition there are the family cate-gories, F-2, H-4, J-2, L-2, and M-2. Some of these family members (spouses and children) may work (e.g., J-2) and some may not (e.g., F-2.)

There are often situations in which an alien could be admitted in one of two or more of the five classes of interest, usually depending on the decision of the U.S. institution involved. For example, a dean of a graduate school grumbled to me about a decision by the Department of Labor [DOL] raising the salaries of some postdocs hired as H-1Bs. He said that, if the salary were raised too much, he would simply bring in the desired worker under his university's J-1 pro-grams.[5] While there are some mild labor standards in most H programs, there are none in the J-l program.

Agencies Controlling the Programs. One final item of general background: What agencies play roles in the control of these programs? Thumbnail sketches of these management patterns will suffice here.

The F and M programs are handled by INS and The Department of State [DOS]. Educational institutions on the INS-approved list are permitted to issue the I-20 form to foreign students to indicate admission to the institution. The student, with the I-20 in hand, then applies to a consular officer for a F-1 visa, which, if obtained, he uses to gain admission at a port of entry. The M program operates in much the same way. A student want-ing to change schools, or to work during a postdegree training period, needs to secure INS approval.

[4] F-1students may work on campus with university permission and off campus with INS permission.

[5] For more on the often very low salaries paid in the postdoctoral positions, see: North 1995:91-95.

All parts of the H program involve both INS and State, and the Department of Labor plays a role in some parts of it. Labor's strongest hand is in the farm program, H-2A, where it helps decide the number of workers to be admitted for a particular farm and then inspects the working and living conditions on the farm. Labor plays a lighter role in the H-1B and H-2B programs, where it sets the prevailing wage for the jobs in question; this was a passive process in the past (with DOL doing little other than collecting paper on the subject) but has become a more vigorous activity in the last couple of years. Labor has no role in the small H-3 program for industrial trainees. An employer in all of these programs must file a petition with INS for the worker in question and, if the petition is approved, the worker then goes to a consular officer for a visa and then to a U.S. port of entry.

The J-program is handled by the United States Information Agency [USIA], by State, and by INS. USIA approves a list of institutions that may participate; they, in turn, issue the IAP-66, the certificate of eligibility for exchange visitor status; the alien then takes the IAP-66 to a consular office, which (usually) issues a J-1 visa that the alien then presents to an INS officer at a port of entry.

The L program is handled by INS and State. The multinational corporation files a petition with INS and, if approved, this leads to a visa issuance by a consulate. If the would-be L-visa holder is in the U.S. legally, then INS can adjust the status here.

Policy Challenges

There are four domestic impacts of nonimmigrant programs:

1. The short-term impact of the program on the U.S. while the nonimmigrants remain in that status (or in some other nonimmigrant classification);

2. The long-term impact on the size of the nation's population created when some of the nonimmigrants adjust to PRA status;

3. The long-term impact when other nonimmigrants opt to stay in the U.S. in illegal status, a factor that is sometimes ignored;[6] and

4. The long-term impact made on the labor market by those staying in the U.S.

In addition, one could discuss a fifth impact, that on international relations. Ideally nonimmigrants have a good time in the U.S. and return to their homes with good images of this country and a desire to buy its exported goods. That would suggest that we: (1) try to make sure that the nonimmigrants are happy in the U.S.; and; (2) that they return when their visa expires. This is an intriguing line of thought, but probably marginal to this task.

The logic of the four kinds of impacts and the four major programs suggests a sixteen-unit matrix, and this can be seen in **Exhibit 2.** The descriptions of the impacts are my own sense of the situation and are designed only to set the framework for the discussion that follows. There is no opportunity in a paper of this nature to present detailed documentation on the costs and benefits of each of these programs. The objective is to sketch what appear to be problem and nonproblem areas prior to a discus-sion of what might be done to resolve the problems.

Short-term impacts. In general terms, all of these nonimmigrant programs seem to be performing well for the institutions that designed them: corporations; the educational establishment; and the immigration bar.

Further, with some exceptions in the H programs, the corporations and educational institutions inevitably obtain what they seek from these programs. Colleges issuing I-20s, for instance, do not have to fight to get their students F-1 visas; it is almost automatic. As we have pointed out elsewhere, the universities and the corporations are the effective gatekeepers in nonimmigrant programs for science and

[6] For example, this possibility is not explored in the otherwise useful paper: Bratsberg Forthcoming.

Exhibit 2.
The Impacts of Four Nonimmigrant Programs on Four Aspects of America
(A Proposed Conceptual Framework)

Nonimmigrant Classes/ Domestic Impacts	F & M	H	J	L
Short-term impact while nonimmigrant status remains	Bland to good on the educational system; minimal on labor market; minimal impact on business	Adverse impact on many labor markets; no impact on educational system; good for business	Some adverse impact on a specialized labor market; good for the educational system; minimal impact on business	Bland on the labor market; none on the educational system; good for business
Long-term impact on size of immigrant population	Mild impact (see data below)	Mild impact	Minimal	Minimal
Long-term impact on size of illegal alien population	Of some concern	Of some concern	Not significant	Not significant
Long-term impact on labor market	Bland, scattered	Of some concern	Bland, small, scattered	Bland, small, scattered

Ratio of Adjustments in the Four Classes of Interest to Total Immigration 1985-1994

	F & M	H	J	L
Adjustments, 1985-1994	243,000	182,000	40,000	63,000
Percentage of Total Immigration	2.5%	1.9%	0.4%	0.7%

Sources: Adjustment data are drawn from Exhibit 1 and its sources; impact descriptions are those of the author.

engineering; people they want are allowed to come to this country, most others are kept out; INS simply rubber-stamps the gatekeepers' decisions (North 1995:37-67).

In some cases, there are few, if any, disadvantages to the society or to elements within it. There may be some adverse effects on U.S. citizen executives in the L program, but I have not heard of them. Easy access of foreign students to American undergraduate education is a good thing for the nation's foreign relations and for the American students who rub elbows with the overseas stu-dents. There are doubts, however, about who is really paying how much for this exchange.

There are some labor market problems implicit within several of these programs, however. In some, the interests of American workers (including student workers) have been ignored out of deference to corporations and universities. (How to strike the right balance among these domestic interests, of course, is a chal-lenge to the Commission and to the Congress.)

The levels of labor market difficulty with the eight specific nonimmigrant pro-grams could be arrayed in the following manner, with the most troublesome at the top of the list:

H-2A (farm workers). This program simply transfers funds from American farm workers to agri-business; it is small but a disgrace;

H-1B. Group entries, as in the case of computer programmers, are needless and lead to worker exploi-tation; single entries are less harmful but need to be reexamined;

J-1. The problem with this program is the total lack of labor standards; many admitted under its provisions are, in fact, full-time workers;

M. This is a small program and its short-term labor market impacts are mild;

F. The short-term labor market impacts are mild;

H-3. This is a small and bland program;

L. This program has no noticeable labor market impacts.

Unfortunately, I have done no work at all on the 15,000-a-year H-2B program; it brings a largely blue collar workforce into the U.S. The workers include, for example, the Jamaican waiters at the Grand Hotel on Michigan's Mackinac Island. I worry about the need for such programs and will leave it at that.

It may be helpful to expand the comments on the two most troublesome of these programs, H-2A and H1B.

As to the agricultural worker programs, I should note that I have had a dim view of them ever since I worked as the Assistant to the Secretary of Labor (then W. Willard Wirtz); my principal assignment was phasing out the *bracero* program, a large-scale farm worker program then lingering on from World War II. We found then, as others have found since, that American employers can do quite well without such programs; that they usually tend to depress wages and working conditions; and that, particularly since the Seasonal Agricultural Workers [SAW] program flooded America's agricultural labor markets, there is no need for temporary worker programs.

My feelings on this subject were, to my great surprise, supported by the recent, grower-dominated Commission on Agricultural Workers. I was sure that the Commission would call for an expanded, easier-on-growers H-2A program, if not a whole new and grower-friendly foreign worker program. Instead it concluded (Commission on Agricultural Workers 1992:133):

> Neither an extension of the RAW program nor any new supplementary foreign worker programs are warranted at this time.[7]

[7] The RAW [Replenishment Agricultural Workers] program was a short-term element of the Immigration Reform and Control Act of 1986 [IRCA] that was never implemented; it would have brought in additional farm workers (presumably from Mexico) had the Departments of Labor and Agriculture determined that there was a shortage of farm workers. The Departments found, in the late '80s and early '90s, that there was no such shortage. The RAW program is no longer part of the law.

The H-1B program presents a much more complex situation.

On the plus side, there are times when an employer genuinely needs an alien who is a specialist in something exotic and no one in the U.S. labor market really has the skills. An oil company, for ex-ample, may really need a Kazak-speaking petroleum geologist to work in both Houston and Alma-Alta. This kind of need, however, is more rare than industry lobbyists will admit.

Also on the plus (or mixed) side of the ledger, is the use of the H-1B program as a transitional status for a U.S.-trained physicist, for example, who is on his way to PRA status. This allows a talented alien to work in the U.S., though it also can add an extra body to a swollen labor force (e.g., the apparent current surplus of Ph.D.s in science and engineering).

The H-1B program also can be used to bring in large groups of foreign-born workers (such as computer program-mers) to do essentially mundane jobs and, often, to displace citizen and PRA workers from these jobs. The employers, given the current minimal levels of labor standards and enforcement, can save substantial funds by providing wages and working conditions that look attractive, say in India, but are well below U.S. levels.

The question then is: How can we preserve the beneficial short-term impacts of the H-1B program while eliminating the well-publicized harmful ones?

In addition to the labor market impacts of some of these programs, there are also some harder-to-quantify impacts on the public purse. Lowered wages and greater unemployment among residents caused by worker displacement in the H and J programs can lead to an unknown amount of lowered tax receipts and increased transfer payments. Further, we have no idea of the amount of public funds spent on educating people admitted in the F and J programs.

Long-term Impact on the Size of the Legal Immigrant Population. Contrary to the somewhat subjective discussion of the short-term impact of nonimmigrants on the U.S., hard numbers in **Exhibit 2** illustrate the first of the long-term impacts, the demographic one.

A very large segment of the nonim-migrant admissions in the four classes of interest does *not* create permanent, legal additions to the U.S. population. There were more than eight million nonimmigrant admissions during the decade covered by the exhibit and only a little more than one-half million cases of adjusted status. There are two reasons for this, one statistical, the other real. First, as noted earlier, admissions, by their nature, overstate the number of people involved. Second, most non-immigrants in these classes do not, in fact, stay in the U.S.

Looking at the demographic impact of these nonimmigrant adjustments in another way demonstrates that, in the same decade, they accounted for only 5.5 percent of the immigrants to the U.S. (counting the legalizations under the Immigration Reform and Control Act of 1986 [IRCA] as immigrants). Adjust-ments from these four classes appear to produce relatively small numbers and a useful segment of the inflow of immi-grants. This is a portion of the immigrant population with a great deal of human capital and, by definition, sustained contact with U.S. institutions and systems.

I understand the Commission's desire to continue a substantial flow of legal immigration, but to reduce its size. I would, however, look to flows other than these adjustments when making most of the cuts. Substantial reductions in these classes would tend to lower the average educational level of the incoming cohorts of immigrants.

People in the four major nonimmigrant classes of interest, however, are not equally avid to become Americans. The statistics on this point are not the best; for instance, an earlier draft of this paper noted the following comparison (drawn from **Exhibit 2**) between admissions and adjustments in the decade 1985-1994:

Class	**Adjustments as % of Admissions**
J	1.9%
L	5.5%
F and M	6.5%
H	11.2%

All of these comparisons of adjustments to admissions cover both workers and dependents, as we are discussing the demographic impact of the nonimmigrants.

Reviewers of the percentages above suggested that it would be better to compare admissions in a given year or series of years to adjustments five years later, on the grounds that this is something like the interval between arrival as a nonimmigrant and adjust-ment of status (for those who follow this course). They also suggested that visa issuance numbers were better than admissions numbers because they approximate more closely the number of people involved in the nonimmigrant population. Good points, both, but they tend to move in opposite directions. The lagging tends to increase the percentages shown above because it relates the number of adjustments to the number of admissions in years when the latter were smaller than in the year of adjustment. The use of visa issuance data tends to move in the opposite direction because the numbers of visa issuances are usually smaller than the number of nonimmigrant admissions.

So, taking nonimmigrant admissions in the four classes for FYs 1985-1989 and the adjustments for the same classes five years later (FYs 1990-1883), I derive the following percentages:

Class	Adjustments as % of Visa Issuances
J	4.0%
F and M	16.7%
L	21.2%
H	38.0%[8]

[8] Data for visa issuances were drawn from *Report of the Visa Office, 1988* table XVI(B) and for adjustments from sources cited in Exhibit 1. One of the problems with the visa issuance data system is the fact that in two of the years covered the Department of State failed to record the number of blue collar H visas it issued (then H-2s) and in the other two years recorded only a tiny fraction of them. To adjust for this, I took half the H-2 admissions reported by INS in those years and added those numbers to the number of H visas that DOS did record. (Thus, I estimate one H-2 visa equivalent for every two H-2 admissions.) The rationale for this ratio is that most of these H-2s were farmworkers and there is a pattern of repeated employment of specific workers in that program. Regarding sugar cane cutters, for example, the U.S. employers and the Jamaican government had directly opposite views on this turnover. The Jamaicans wanted to spread the work among the rural poor, the employers wanted to hire back those workers known to be energetic (and docile); so they split the difference, with 50 percent of each cohort of cane cutters being newcomers and 50 percent being predesignated experienced cutters. One wonders if DOS recognized the implicit symbolism of its statistical policy in those years, i.e., that farmworkers do not count.

In both the cruder and in the more careful comparisons, the class relationships are about the same; exchange people are the least likely to adjust, workers are the most, with the student and international executive classes in the middle.

It makes sense that members of the H class were the most likely to adjust; they are employed on a temporary basis by U.S. employers and many are in a trial period. If things go well, the employer will seek a green card for them. My work with foreign-born scientists and engineers suggests that many of the foreign-born, U.S.-trained Ph.D.s who stay in the U.S. use the H-1B status as the springboard toward the green card. Most of the H class nonimmigrants adjusting to PRA status do not have the education level of the scientists and engineers, but they do have, by definition, good ties to the U.S. labor market because, in most cases, it is their H class employer who files for the labor certification.

It is not clear why the adjustment rate is not higher than it is for the Ls; they, too, are employed in the U.S. and the immigration law makes it easy to adjust them to PRA status. Maybe many of them are genuinely multinational people working for multinational corporations, simply spending some time in the U.S. during a career that will take them to several countries.

The lower rates of adjustment for the student classes does make sense; they usually are not linked to an American employer while here unless they wish to follow an academic career.

Drifting Into Illegal Status. One suspects that some substantial, but unknown, portion of the lower income nonimmigrants in the classes of interest—blue collar workers and vocational students—tend to drift into illegal alien status. Certainly this happened with substantial numbers of the Mexican nationals who came to the U.S. to work as *braceros* (farmworkers) in the 1943-1964 period.

There are, however, no data sets that are helpful in this regard, and the current and recent INS enforcement strategies—with the concentration on the borders and on

criminal aliens—suggest that INS deportation data can be of little help. The suspicion lingers, however, that some of the blue collar nonimmigrants, and a few of the white collar ones, stay illegally in the U.S.

Long-Term Impact on the Labor Market. In three of the major nonimmigrant classes (F & M, J, and L) I sense that the long-term impact of their adjustment to PRA status is generally bland (perhaps a little less so with J than the others). But I am worried about the lingering labor market impacts of many of the H adjustments.

My understanding is that, when there are *concentrations* of alien workers in a given labor market (be it defined occupa-tionally or geographically), there are likely to be problems of labor market distortion—lower than normal wages, higher than normal unemployment. These problems are likely to be aggravated when the workers involved have few rights or few perceived rights (such as the H-2A farm workers and the newly-arrived Indian programmers). Further, when these problems exist, there is usually some controversy; the complaints may be ignored by the decision-makers, but the complaints are there.

There appears to be little to worry about with the adjusting students or the intra-company transferees on either ground. The adjustees seem to be scattered and the complaints minimal to nonexistent.

But there is plenty of noise about some of the lingering aspects of the H-1B program, at least within the fields of science and engineering. It appears that the whole, seamless web of easy access of talented aliens to U.S. graduate schools, generous U.S. funding for these aliens at those graduate schools, world-wide peace, and (unfortunately) reduced government funding for research and development has led to an overpro-duction of Ph.D.s in science and engineering. The H-1B program then facilitates the entry of the foreign-born Ph.D.s into the U.S. labor market. The only clear beneficiaries of this situation are the institutions doing the training. There appears to be a need to reduce this

overproduction; how this should be done—by changing nonimmigrant or other government policies—is discussed later.

How Nonimmigrant Policy Is Made; Also, Three Precedents, Two Works in Progress, and One Continuing Problem

Nonimmigrant policies are made in the United States by legislators, but in most of the rest of the world this is done by administrators.

Such policies in the U.S. are highly legalistic, detailed, and subject to substantial reviews by the courts. This is not the case in the other democracies.

In the U.S., immigration policy usually consists of four elements: (1) definitions of eligibility for a benefit; (2) statutorily-fixed numerical ceilings on that benefit; (3) waiting lists; and (4) little administrative flexibility except for the possibility, sometimes, of waivers and paroles.

The other two prime, self-recognized nations of immigration (Australia and Canada) have used more flexible targets (annually adjusted) to control the size of immigration and more flexible points systems to decide on whom to admit.

Until recently, U.S. nonimmigrant policy contained no legislated ceilings—if one alien or ten thousand could prove their eligibility, they were admitted. The 1990 Immigration Act, however, broke that pattern by imposing a 65,000 ceiling on the number of H-1B petitions to be issued in a single year.

U.S. nonimmigration policy also is suffused heavily with efforts to create, artificially-level playing grounds for U.S. workers and their nonimmigrant peers. Thus, the Department of Labor for years adjusted the H-2A adverse effect wage rate; if a grower could show that he was paying at that rate and was unable to secure needed workers (usually a month or so before they were needed), he could secure the foreign workers he wanted. The artificiality of this process was further accentuated because in real life farm work is compensated by piece rates and the

adverse effect wage levels were hourly rates.

Similarly, H-1B employers are supposed to pay their foreign workers at no more than 95 percent of the prevailing wage for the job in question, a shaky concept at best. And why only 95 percent?

The Commission needs to bear these traditions in mind as it approaches the matter of reforming nonimmigrant policies.

I now turn to three interesting precedents in nonimmigrant and labor standards policymaking and to two works in progress.

The Visa Waiver Precedent. A few years ago the U.S. decided to try an experi-ment: to retain its general policy of demanding a visa for all incoming nonimmigrants, but to waive it under certain conditions for people from certain nations. The twin driving forces were to make it easier for tourists to come to the U.S. and to reduce largely useless work-loads for the Department of State overseas.

So the U.S. worked up a (now slowly expanding) list of nations whose residents rarely become illegal aliens; they could come to the U.S. without a visa if they bought a nonrefundable airline ticket and if they signed away their right to contest a (highly unlikely) INS decision to exclude them on their arrival at a U.S. airport. The experiment has worked well, millions use it, and only a handful have abused it. (I get to the utility of this precedent later.)

The Australian Student Visa Program Precedent. Australia's nonimmigrant program for students makes sharp distinctions, just as the U.S. visa waiver program does. There are "gazetted" and "nongazetted" countries, with the latter having lower incomes than the former and, presumably, higher degrees of abuse of Australia's immigration law.

Australia also makes a sharp distinction between "nonaward" students (those not heading towards a degree) and "award" students. If you are from Tonga and want to take a thirteen-week English language course, for example, you fall into both the nongazetted and the nonaward categories

and you are told in a government announcement that your chances of getting a student visa are slim (Commonwealth of Australia 1994).[9]

The California Labor Standards Precedent. The California Department of Industrial Relations enforces the state minimum wage, which is sometimes higher—and always more vigorously enforced—than the federal minimum wage. One of the reasons for the greater vigor of enforcement is that California has found a way to supplement tax funds to support this operation.

Fees and fines collected by the Department of Industrial Relations go into the agency's own budget. An employer of hourly workers, for example, is fined $100 every time a state inspector finds that a worker is on the shop floor but that there is no timecard for that worker (North 1991:54-55).

Work in Progress # 1. The U.S. Department of Labor is making efforts to bring higher labor standards into the H-1B program and to penalize abusers of the program.

In a recent action, for example, it worked out a settlement with Syntel, Inc., of Troy, Michigan, in which the firm agreed, among other things, to: pay additional wages to previously underpaid H-1B computer programmers; pay $30,000 in civil penalties; not hire any more H-1B workers for ninety days; and invest $1,000,000 in its training programs for U.S. workers (Interpreter Releases 1995b:1261-64).[10]

Work in Progress # 2. Worried by the possibility of terrorist acts by a small minority of foreign students and citing the World Trade Center bombing and the murders at the gates of the CIA, INS has created a Task Force on Foreign Student Data System Reengineering.

The general notion is that the govern-ment should keep closer tabs on foreign students and should create a data system that will track them while they are in this

[9] I am grateful to Christopher Smith, Counsellor and Consul at the Australian Embassy in Washington, for providing me with this publication.

[10] For an earlier report on a similar subject, see: *Interpreter Releases* 1995b:1-4.

country. While the subject is not mentioned explicitly in the draft report of the task force, the thrust of the pro-posed activities also would tend to discourage F students from drifting, unwatched, into illegal alien status.

The task force makes a number of proposals, in addition to a compre-hensive reporting system for individual students, such as:

- Eliminating the power of public schools to issue the I-20;
- Reviewing the list of INS-approved schools from time to time to remove educational institutions that rarely issue the I-20;
- Collecting a fee from each foreign student, via the educa-tional institution, to finance the tighter regulation of the program.

Presumably the task force's program will have no impact on the easy flow of genuine international students (except making it a little more expensive) but will tend to discourage the drift into illegal status. It apparently will have no labor market impacts.

One Continuing Problem. It is always easier to obtain public funding for some activities than others; it is, for example, usually easier to hire more cops than to employ more librarians.

So it is within the Immigration Service. Time and again the Congress will vote to hire more Border Patrol Agents and to equip them with newer and fancier tools, helicopters, sensors, and the like. But it is very hard to obtain what INS gently calls "alien travel money." These are the funds used to buy plane tickets for aliens being deported.

For instance, earlier this year, INS launched a major new initiative to reduce the backlog of asylum applications and to discourage ineligible applicants from filing. The principal new tools were: (1) a delinking of the application for asylum and the issuance of a work permit, thus eliminating the incentive of an instant work permit when filing for asylum; and (2) the hiring of additional officers and

judges to handle the new cases more quickly.

One of the INS assumptions was that with the new system—a multimillion dollar investment—there would be more people being found ineligible and, thus, deportable. Although the system came into being on January 4, 1995, and was due to start causing some deportations in a matter of months, only $100,000 was made available in alien travel funds for the balance of the fiscal year.

The lack of alien travel funds is a recurring problem within INS; I remember a few years ago the inves-tigators in the New York District Office were told: Concentrate your enforcement activities on locating two types of illegal aliens, ship jumpers and stowaways. I asked if they were especially dangerous and was told, "No, but the carriers have to pay for their removal and the district is out of alien travel money for the rest of the fiscal year." I return to this point later.

General Recommendations

Bearing in mind the previous discussion, I have several general recommendations for the reform of the work and education-related nonimmigrant programs.

1. **Limit the number of nonimmigrant classes.** The more classes, the harder they are to administer; the more classes, the more loopholes; the more classes, the more confusion in the using publics, institutions, and aliens.

2. **Limit the number of government agencies involved.** Many nonimmigrant programs now involve the Departments of State, Justice, and Labor; the multidepartment involvement is not desirable but it is, in the short-term, probably unavoidable. What can be done, however, is to eliminate the United States Information Agency and its control over the J-1 program. USIA has said it

wants, desperately, to get out of the *au pair* program; let us assent to that—and more—and remove USIA from the supervision of all exchange programs. If it wants to operate an exchange program of its own (under the general eye of INS), that is all right.

3. **Enforce the rules.** In addition to fewer programs and fewer agencies, it is vital that we have more governmental control over the nonimmigrant programs to discourage the slippage of legal aliens into illegal status and to protect against labor market abuse.

4. **Raise enforcement funds from those using the programs.** Individuals, and particularly institutions, using nonimmigrant programs should pay fees to support enforcement measures. INS has, over recent years, raised a great deal of money from individual aliens seeking benefits, and it is starting to collect some fees at the borders. Good. It also should begin to charge break-even fees on some transactions, such as the issuance of the I-20, to fund enforce-ment within the F program. The California Department of Industrial Relations has set the precedent for such fees.

   Further, and for a different reason, INS should start charging substantial fees for accepting (not necessarily for approving) H-1B petitions, as is proposed in pending Senate legislation.[11] The notion here is that the employer will probably pay more attention to his options within the American labor market if there is an upfront fee, of say 10-25 percent of the H-1B worker's wages.[12]

5. **Make distinctions, painful though it may be.** It makes sense to concentrate resources where there are problems and to invest lightly in nonproblem areas. It also makes sense, as in the U.S. visa waiver program and in Australia's foreign student program, to make distinctions among nations, and, as in the

[11] This paper was written in January 1996.

[12] If these fees are levied, there needs to be a mechanism to see to it that the employer, not the newly hired foreign worker, pays the fee.

case of Australia, among educational programs. (Remember the non-gazetted, nonaward students.) The U.S. also should make distinctions among types of work and types of corporations—we know that some are much more troubling than others.

In the H-1B program, for example, we do not do the obvious; we do not set much more stringent standards for group usages of the program than for singleton usages. If, as some have suggested, binational corporations in the temporary worker business are more likely to cause problems than domestic corporations, we should not shrink from focussing on the former, even though one set of executives may be foreign-born while the other is native-born.

6. **Introduce the nonrefundable, life-time, round-trip air ticket.** To ease the return of aliens when their visas are over and to fund their departure if they become deportable, the U.S. should impose a universal require-ment on all nonimmigrants arriving by air (and sea). That is, they must buy a nonrefundable, round-trip ticket that is good for the rest of their lives.

Why should any one arriving on a nonimmigrant visa object? They have, after all, sworn that they are *not* going to stay in the U.S. Why not use the visa waiver precedent in this regard?

The presence of the ticket (probably both a hard copy and a record in a computer) would mean that the alien could always afford to return to his or her homeland. Broke in the U.S.? Tempted to take a job illegally to raise some money to go home? Don't bother, you have that life-time return ticket waiting to fly you back home. The ticket also would mean that alien travel money never again would be used to transport overstays, those funds could be focused entirely on those entering without inspection [EWIs].

The airlines, of course, will object. It would add an externally-caused complication to their internally-caused tangle of ticket prices. They would have to train their com-puters and

their staffs to handle a new set of variables.

But it would allow them to raise their international fares and to keep the extra money as an interest-free loan, a short-term one in some cases, but a very long-term one for someone who successfully entered the U.S. by air and then became a long-term undocumented alien.

7. **Cease legislating immigration via treaties.** While the Free Trade Agreement nonimmigrant provisions have made major changes in the way we make policies in this area, no substantial adverse impacts have been seen—yet. But the whole notion of giving a set of diplomats control over migration policies is startling to say the least. There are no congressional hearings and no organized input from interest groups; migration decisions are buried deep in agreements that deal largely with totally different and more pressing issues. Further, the whole process is in the hands of a department (State) that is always emotionally distant from the lives of working Americans.

   The Commission should take a stand that Congress should *never* again let immigration or nonimmigration policy fall into the hands of the treaty makers.

8. **Create a whole new nonimmigrant system.** Legislative policymaking in the U.S.—at least before January, 1995—was usually a piecemeal process. Laws and systems would evolve slowly and change a little bit at a time. With that in mind, the final section of this report makes a series of suggestions about modi-fying (or in some cases dropping) the current group of nonimmigrant programs.

But supposing we could ignore the current litter of nonimmigrant programs and create a new system from scratch. What would it look like?

Let us limit this exercise to the five nonimmigrant categories discussed above (as well as the new Os, Ps, and Qs).

Instead of these eight classes, with their subclasses, I propose:

- Students and Scholars;
- Temporary Workers;
- Transitional Workers;
- Intracompany Transferees.

In general terms, Students and Scholars [S&S hereafter] would be a merger of the F, M, and Q programs with most of the J program.

Temporary Workers [TW] would cover most of the H programs, the workers now within the J program, as well as the Os and Ps.[13]

Transitional Employees [TE] would be people holding short-term jobs in the U.S. but on their way to PRA status; most people in this category currently are a subset of the H-1B class.

Intracompany Transferees would be essentially the current L program, which would not be changed.

S&S would be administered by INS alone; the Department of Labor would set labor standards and help enforce the other three programs in cooperation with INS. USIA would not be involved, and State would continue to play the visa issuance role.

There would be no need for labor standards in the new S&S program because, except for incidental work by undergraduates, all working graduate students, postdocs, and faculty on short-term assignments would be regarded as workers in the TW class.

Labor standards would be set for the TW, TE, and Intracompany Transferee classes. (The last named could get along with a simple minimum wage for multinational executives, say $40,000 a year, to rise annually with inflation.) And with labor standards being set by a single agency, institutions would not have the opportunity, as they do now, to comb through various categories seeking the best deal (or the lowest wages).

[13] Os are workers of outstanding ability, Ps are entertainers and athletes, and Qs are a group of culture exchange people. These categories were added by the 1990 Act.

The TE class would be set up deliberately as a way station to green card status. It would recognize and preserve the most useful part of the H-1B program, while separating it from the group admissions aspect of the current program.

Demetrious Papademetriou and Stephen Yale-Loehr have suggested an interesting way to select members of the TE class; successful candidates would have to earn enough points in a system that also handles labor-related permanent immigration.[14] A point system could be managed by the government in such a way as to minimize the current glut of science and engineering Ph.D.s, for example, and yet open the doors for more of them should the need arise later. More significantly, it would cause corporations to hire from among a group of aliens with characteristics needed by the nation in the long haul—as opposed to choosing H-1Bs to meet the narrow needs, some-times the whims, of an individual cor-porate manager.

As a part of my larger scheme, then, only TE and Intracompany transferees could adjust to PRA status on the basis of labor needs; people in the temporary worker [TW] and scholars and students [S&S] categories could adjust to PRA because of family reasons, as they can now, or to the new TE status should they qualify. One also could come to the U.S. with a TE visa in addition to adjusting to it from some other nonimmigrant category within the U.S.

This would leave us with four nonimmigrant classes of workers and scholars, with an integrated system for the making of governmental decisions, and with a clear-cut set of standards for all involved.

But if all we can do is adjust the current system, the next section provides some more narrow suggestions.

Specific Recommendations

Within the current framework, I would suggest the following changes.

First, and foremost, adopt the mandatory, nonrefundable, lifetime-long, return airline ticket for all incoming nonim-migrants. If they have such a ticket, they will be a little more likely to return when their vi-

sas expire. If they do not return, and fall out of legal status, they can be sent back at no public expense.

Now, regarding the specific classes of interest:

F-1: Academic Students. It is a good idea to keep foreign students coming in, learning in, and then leaving the country. This is what most of them do, and this is to be encouraged.

I am concerned, however, with the question of who is paying the bill and suggest an approach to this problem in **Appendix A**. I share the view of the INS Task Force that the F program should be tightened administratively and that funds for this be raised by charging a fee for the issuance of the I-20.

In addition, there is something that INS and the Department of Education [DOE] should do that I believe is not yet in anyone's plans. DOE has identified a group of educational institutions where students have a high rate of failure in repaying DOE loans. My suspicion is that these are the kinds of institutions (often proprietaries, often providing vocational training) that do not provide foreign students a good education, either, and that F and M students in these places are more likely to drift into illegal status than other foreign students. DOE and INS should get together and jointly assure that these institutions no longer can issue the I-20 (or the M program's version thereof) nor use the federal loan program.[15]

H-1B: Specialty Occupations. This is a large program with many nooks and crannies. Sometimes it is used for the actual importation (from overseas) of individual workers with remarkable skills for short-term assignments in the U.S.; sometimes it is used to hire individual talented workers already in the U.S. in another status; sometimes it is part of a many-stage process by which a foreign-born, U.S.-trained worker moves towards PRA status (as is

[15] Late in this writing I recalled the McDonald's amendment to INA, setting up a special work program with that kind of firm for F students. I also recall that the Bureau of International Labor Affairs [ILAB] at DOL has studied this matter. I would hope that the Commission has seen that report, which, I think, was discouraging in tone.

often the case with scientists and engineers). All of these uses are acceptable to commendable.

The worrisome part of the same H-1B program is its use to bring in *groups* of journeymen technicians and computer programmers at relatively low wages; such workers depress wages and working conditions in the U.S. and often displace U.S. workers. This part of the program should be eliminated or severely curtailed.

For detailed suggestions as to how to do this, see **Appendix C**.

H-2A: Farm workers. Abolish the program.

H-2B: Other Temporary Workers (mostly blue collar). I worry about the exploitive nature of such programs here and abroad but have no first-hand knowledge of this particular program and, hence, make no suggestions.

H-3: Industrial Trainees. This appears to be a small and noncontroversial program, so reform energies should be directed elsewhere.

J-1: Exchange Visitors. Again, as with the F-1 program, it is a good thing that a cosmopolitan mix of people is coming to the U.S. to study, confer, and work with their U.S. peers on a wide variety of subjects and in a wide variety of institutional settings

Within this useful program, however, there are places where nonimmigrant graduate students, postdocs, and others are treated very badly. There are no labor standards in the J-l program, though many people in the program work for wages and do so for years at a time.

Labor standards should be introduced into this program as it stands or, perhaps better, exchange visitors, who are in fact workers, should be moved out of this program and into a temporary worker program run by the Department of Labor. The universities, of course, would not like that, and the people who would benefit—the foreign scholars and their U.S. peers—are hopelessly ill-organized for such a struggle with the splendidly-organized educational establishment.

M-1: Vocational Students. It probably was a good idea—if against the thrust of

the suggestion that there are too many programs—to separate vocational schools from academic ones.

Someone should examine this program to see if it is worth continuing. Caution is suggested by the general record of private, forprofit vocational schools.

What clearly must be done, as suggested with the F-class institutions, is for INS and the Department of Education to share information on marginal insti-tutions and for both to move swiftly against those entities that either create a high percentage of illegal aliens or whose students fail to repay DOE loans.

Adjusting from Nonimmigrant to Immigrant Status. This subject is at the edge, perhaps beyond our charge. But, with the seamless movement from one nonimmigrant status to another and then on to PRA status that I found so common among the scientists and engineers, perhaps a final set of comments is in order.

I am concerned about the apparent current overproduction of Ph.D.s in science and engineering and worry that the current easy adjustment from non-immigrant to immigrant status will aggravate that surplus, given the large number of highly-qualified, foreign-born Ph.D.s in the country and in our educa-tional pipelines.

On the other hand, reduction in research and development investments at the federal level, which would slowly reduce the surplus,[16] seems a terrible idea, and barring Ph.D.s and other highly-educated aliens from immigrant status simply would press down the average educational attainment levels for the arriving cohorts of immigrants.

Several other suggestions have been made about how to cope with this surplus. One I favor has the disad-vantage of being very slow-acting: impose on federal research grants a quota on nonimmigrant graduate students—to no more than, say, one-third of the graduate students funded.

[16] By reducing the funding of such research, the number of foreign-born graduate students funded to study in this country would be similarly reduced.

This would, over time, reduce the number of nonimmigrant Ph.D.s educated here at our expense and probably would push the universities to look a little more carefully at the domestic talent pool. It also would allow the continuation, at slightly lower levels, of a useful pattern—the training of some of the world's best minds in some of the world's best university laboratories.

Another option would move much more quickly: impose a two-year overseas requirement before any adjustment could be made from nonimmigrant to immigrant status. This is a dusting off, expansion of, and enforcement of the old two-years-overseas rule, which once played a major role in the J program but since has been watered down by a series of waivers. The problem with this is that it would be immediately disruptive, in that for two years no one in the current path from nonimmigrant to immigrant status could make that move.

Yet another proposal would be to levy a substantial fee on adjustments from nonimmigrant to immigrant status of, say, 25-40 percent of the individuals' salaries.[17] This seems to make sense; corporations and universities probably would ask for fewer adjustments and those that they did seek would be the very best. The change would be more gradual than the abrupt imposition of the two-year rule, but more assertive than my suggestion of a one-third limit on funding of nonimmigrant graduate students. The combination of both of these proposals (the one-third quota and the stiff fee) would continue a useful international educational program but limit its impact on American labor markets.

APPENDIX A: A Note About Who FInances Foreign Students in the U.S.

One of the difficulties with working with nonimmigrant policies *vis-a-vis* foreign students is the abundance of misin-formation distributed by the educational establishment on who pays the bill for

[17] The Department of Labor wants to use such fees for training Americans in the apparently needed skills; I would lean to the use of most of such money for the enforcement of labor standards in nonimmigrant programs.

educating foreign students in this country.

It will be difficult to impossible to make appropriate policy in this area as long as the impression remains that American universities—like Iowa's soy beans and Hollywood's movies—are major earners of export dollars. I do not think this is the case; the data offered to support that case are faulty (North 1995:77-85).

What policymakers need, and do not have, is a nationwide set of per-student estimates of the elements listed below. They will, of course, differ from insti-tution to institution, but if we had them for a good sample of America's colleges and universities, we would have a better sense than we do now of who really pays for foreign students. The per-student, per-year estimates we need are:

1. Public moneys subsidizing the institution;

2. Private moneys (such as earnings on endowments) doing the same;

3. Public and private funds subsidizing individual foreign students (on average);

4. Moneys earned in the U.S. by such students during college years and spent on college-related expenses;

5. Moneys brought to the U.S. from overseas to support the education of such students.

Were we to have this information, then we would know the extent to which foreign students were supporting their education with money from foreign sources. We would probably find that numbers 1 + 2 + 3 + 4 (U.S. sources of funds) in most circumstances over-whelmed item number 5 (foreign sources) because of the hidden subsidies that wash over much of higher education in this country, benefitting foreign and domestic students alike.

But the educational establishment does not approach the question in that way. It does so in a way that produces headlines like this: "Foreign Students Pump up Economy" (*USA Today* 1995). This uncritical story was a rewrite of an Institute of International Education [IIE] press release on the subject.

Let's switch gears for a moment and assume that someone decided to conduct a survey on what the voters thought of

President Clinton (instead of who pays for the education of foreign students). The pollster would ask his question (dealing with only part of Clinton's work) and would provide four alterna-tive responses:

The question:

> "Voters think Bill Clinton is doing very well with his foreign policy, don't they?"

The alternative answers:

___"Yes, he is doing very well;"
___"Yes, he is doing well;"
___"He's doing okay;"
___"No, he's not doing well."

The question in our metaphoric survey is not to be asked of people generally; it is to be asked of Democratic precinct captains.

A survey with such loaded methodology would not be used by the most desperate of political consultants, but that is *exactly* what IIE does annually.

It does not seek information on the whole question, on the relative significance of the five previously cited flows of funds. Nor does IIE seek hard data on this subject from university budget officials or from the students themselves, the people who would know best; no, it asks for perceptions on this point.

It does not ask the perception question of neutral observers, either; it seeks the perceptions of the foreign student advisers—the moral equivalent of polling the Democratic precinct captains.

Finally, after loading the design of the survey, IIE also loads the ballot. Following the question (primary source of funds) it provides the potential answers:

"Personal and Family;"

"U.S. College/University;"

"Home Government/University;"

"U.S. Government;"

"Private U.S. Sponsor;"

"Private Foreign Sponsor;"

"International Organization;"

"Current Employment."

And, lo and behold, every year the patterns of the response fall almost perfectly

into place, mirroring the sequence of potential responses, with the answers being respectively 66.2 percent, 19.0 percent, 5.2 percent, 1.4 percent, 2.8 percent, 2.0 percent, 0.5 percent, and 2.3 percent (IIE 1992).[18]

I have called this to the attention of IIE by letter,[19] and, sought, on three different times, to interest three different editors of the *Chronicle of Higher Education* (which ran a long, careful report on our recent book), but no one would touch the presumably interesting, perhaps explosive, question of how IIE was loading the survey's dice.

I had been vaguely aware of the *Open Doors* survey results on this point for years, and had accepted them unthinkingly. Then I ran into a com-pletely different set of results on this subject. These were from the *Summary Report 1991: Doctorate Recipients from United States Universities* (NRC 1993:18).[20] The National Research Council [NRC] had asked the same fuzzy question. (Regarding the primary source of funding—why Ph.D.s can not be asked about the *percentage* of their funding from various sources is beyond me.) The NRC answers were totally different from those elicited by the IIE:

Population	Primary Source of Funding	
	Personal	University
All foreign students (IIE)	66.2%	19.0%
Nonimmigrant Ph.D.s in physical science and math (NRC)	4.0%	89.1%[21]

There are three reasons for these differences: first, science and engineering students are more likely to receive funding than others; also graduate students

---

[18] See, for example, page 149 for the questions asked the foreign student advisers and page 37 for responses. The same ballot pattern and roughly the same responses can be seen in other editions of this annual report.

[19] I suggested that the least IIE could do would be to change the sequence of the multiple-choice responses from year to year, as responsible pollsters do, but there was no answer.

[20] The nonimmigrant Ph.D.s in life sciences (7.0 percent) and in engineering (8.6 percent) reported slightly higher dependence on personal resources than those in the physical sciences.

[21] Most of this consists of federal research dollars spent through the university and is identified by the Ph.D.s as university, not federal, moneys.

(as IIE's own data suggest) are more likely to be assisted than under-graduates. But the third reason relates to the fundamental point made earlier—NRC asked the question of people with direct, unbiased knowledge on the point, the graduate students themselves.

A Suggestion. It would be useful to have a better notion than that provided by IIE's flawed data and by NRC's narrow data (on Ph.D.s only) regarding who pays for the higher education of nonim-migrants in this country.

While a total census of the finances of foreign students would tell us exactly how these matters play out, a far more modest study could provide us with the basics needed. What I would suggest would be a sample of some forty to sixty institutions of higher education, with the appropriate mix of private and public entities, those large and small, those rich and poor, and those with large and small percentages of nonimmigrant students.

The research would involve four tasks: first, and easiest, an analysis of the extent to which public and private funds were used in a recent year in each institution to fund the education of all students, foreign and domestic; the basic question, what portion of the total cost of a year's education (including room and board) was subsidized? This would cover items number 1 and 2 [see above].

The second task would be a files search in the student aid or foreign student office of a sample, say twenty-five, of the foreign students on campus. This should provide information on the extent to which individual assistance was offered to the students in the sample and the extent of on- and off-campus employment.

The third task would be to calculate the total cost of a year's education for the average foreign student, including institutional subsidies, tuition paid, and room and board. From this one would deduct the subsidies, loans made to these students from U.S. sources, as well as financial aid and wages for employment; the residue presumably would represent the moneys coming to the U.S. as a result of the arrival of the nonimmigrant student.

The fourth task would be to interview a subsample of the foreign students studied through the file searches to check on the accuracy of the files search process.

Perhaps GAO or the Department of Education could be encouraged to mount such a study as the Commission ponders the nation's nonimmigrant policies.

APPENDIX B: A Note About the U.S. Islands

While the Commission presumably is spending 99.5 percent of its energies on the immigration challenges to the fifty states, it should not lose track of the difficult immigration policy questions of the U.S. islands in the Pacific—Guam, where the mainland immigration law applies and American Samoa and the Commonwealth of the Northern Mariana Islands [CNMI], where the law does not, but should.[22]

While the mainland has some controversial nonimmigrant worker programs (computer programmers and sugar cane cutters, for example), they are models of generosity compared to the way that foreign workers are treated in American Samoa and, particularly, in the Marianas.

The exploitation in CNMI's sewing factories is well known on the mainland—the miserable wages, the life behind barbed wire, the long hours, the terrible working conditions and the products all labelled "Made in the U.S.A."

Perhaps less well-known are these two simple facts: (1) there are more guest workers in the Marianas than citizens; and (2) Congress can restore its control over

[22] The INA covers Puerto Rico and the U.S. Virgin Islands; international migration to Puerto Rico is minimal and, although the Virgin Islands once had a controversial temporary worker program, that matter was resolved long ago. While there are universities in Puerto Rico, the Virgin Islands, and Guam, I have not encountered any discussion of the foreign student programs as a problem on any of these islands. CNMI and American Samoa do not have four-year colleges and, besides, they have much more vigorous deportation policies than the mainland, so, if they have problems with foreign students, they presumably do something about it.

the CNMI immigration policy by merely passing a statute.[23]

The exploited workers in CNMI are mostly women and primarily from China and the Philippines. They are different from the citizen population in the Marianas, the Chamorros. And, under current CNMI law, they never can be-come citizens of the Marianas or of the U.S.[24]

Further, there are elements of sexual exploitation in CNMI that have not surfaced with mainland temporary worker programs. The largely Chamorro male CNMI immigration service is notorious for the way that many of its officers harass the nonimmigrant women; some of those women wind up as prosti-tutes. It is grim situation.

The problems in American Samoa are less publicized and less brutal. Among other things, the exploited class at the moment is another group of Samoans, citizens of Western Samoa; the migrants speak the same languages as, and intermarry with, the dominant population. Western Samoans do the dirty work in the fish-canning plants in Pago Pago, while American Samoans have the softer jobs in the overstaffed local government. Western Samoans cannot become citizens of American Samoa, or more formally, U.S. Nationals, but their children can, provided they were born in the U.S. ter-ritory. Both CNMI and American Samoa have real *nonimmigrant* policies—in that they do not have significant provisions in their local immigration laws for immi-grants, only for guest workers.

While there is extensive unemployment in American Samoa, the local govern-ment recently has approved the impor-tation of several hundred Chinese women to work

[23] The new CNMI Governor, Froilan Tenorio, is making a much stronger effort to limit the abuses in the nonimmigrant program than his predecessors, but he wants CNMI to continue to make immigration decisions.

[24] The imbalance of power between the citizen population and the guest workers in CNMI is more like the situation in the Trucial Sheikdoms than it is on the U.S. mainland. For instance, there are frequent stories in the local press of Chamorro families *on welfare* hiring (and failing to pay) nonimmigrant servants (see, for example: Phillips 1995). Governor Tenorio has been trying to end this practice.

in a new, offshore-owned sewing factory; their stated role is to be instructors in industrial sewing, but they will stay for years, housed in a company barracks. It is well-known that it takes only a couple of weeks, at most, to teach someone how to use these machines. The Chinese will be a docile workforce; they will be used to press the Samoan workers to greater heights of productivity as they sew in the labels: "Made in the U.S.A." The mainland minimum wage of $4.25 does not apply in either Samoa or CNMI; the local minimum wage levels are much lower than in the fifty states and much less well enforced.

Meanwhile, in the third remaining U.S. island in the Pacific, Guam, the INA controls, but there are strong local traditions of heavy use of the H-2B program in construction and in the services. (Guam, like CNMI, is a tourist attraction to a subset of the Japanese population—the ones with enough money to travel, but not enough to travel very far.)

Many interest groups in Guam would like the island to control its own immi-gration policy; there is a strong desire for more cheap labor, in the CNMI tradition, and a strong nationalist desire *not* to grant citizenship to newcomers.

I have been covering immigration and labor market trends in these islands—from Washington—for a decade as the American correspondent for Fiji's *Pacific Islands Monthly*. My advice to the Commission is to see to it that Guam stays under the wing of U.S. law on this point and to encourage the Congress to restore its domain over the Marianas' immigration policy. It also might be a good idea to let the American Samoan Government know that Washington is watching its handling of its foreign workers.

APPENDIX C: Detailed Recommendations on the H1-B Program[25]

As noted earlier, the Department of Labor has proposed some useful initial steps

[25] Adapted from North 1995:171-73.

towards reducing some of the abuses in the H-1B program. It needs to go much further, but first it must acknowledge the basic difference between the use of the program to bring in single workers—and groups of workers. The latter is *always* more harmful both to resident workers and to nonimmigrant workers themselves.

To this end, DOL and other government entities should take the following steps:

Fee structure. There should be a graduated fee schedule—the more nonim-migrant workers an employer wants, the more each costs. Fees should be levied on all applications, whether or not they are approved.

Differential Scrutiny. As a matter of conscious practice, the Department of Labor should announce that it will pay much more attention to applications for groups of people than single applications.[26]

If an application for more than ten workers is received from a single facility, for example, DOL investigators should make site visits, preferably unannounced, to talk with individual workers, both foreign-born and native-born (away from management's eyes and ears) about wages and working conditions. The fees to be paid by those seeking H-1B applications should be used to fund these investigations.

Notice. To make sure that all taxes are paid and to make certain that arriving H-1Bs know exactly what their actual pay checks will be, employers seeking three or more H-1B workers in the course of a year should be obliged to have an exchange of correspondence with their would-be workers outlining wages and deductions. Currently there is no obligation on the part of an H-1B employer to tell his nonimmigrant worker about the extent of federal income tax, state income taxes, FICA, and Medicare deductions, nor about the standard 30 percent deduction required by IRS for nonresident aliens.

Further, copies of these exchanges of correspondence should be filed by the employer with:

[26] One potential problem, of course, is that mass users of H-1Bs will seek to camouflage their activities by creating subsidiary corporations, assigning workers to subcontractors, and the like.

- All pertinent federal, state, and local taxing authorities;
- Unions, where present;
- Pertinent technical or profes-sional organizations, and;
- The trade press.

Prevailing Wage. The arrangements currently made for determining the minimum wage are inadequate, as is the puzzling requirement that the employer has to pay only 95 percent of whatever is found to be the prevailing wage. Why not 105 percent to encourage the employer to pay attention to resident workers, be they citizens or legal immigrants?

Instead of using the hard-pressed and underfunded State Employment Security Agencies to establish prevailing wages, why not use the generally available, occupationally-specific, salary surveys of the various professional and engineering societies?

In this scenario, if the employer wanted to hire a chemist with a bachelor's degree and two to four year's experience in 1993, for example, the employer would be required to pay the prevailing wage for such workers as established by the American Chemical Society's annual salary survey, or $33,300. Chemists with a master's degree, two or four years after the B.S., would get $39,000. The ACS survey, as currently conducted, does not provide a prevailing wage for a new Ph.D, but a chemist with a doctorate five to nine years after the B.S. received $53,000 in 1993 (Heylin 1993:10).

These salary surveys reflect the workings of the national labor market and presumably would be regarded as appropriate by the workers involved. The salary scales are easily obtainable by employers (from the trade press) and are not vulnerable to manipulation; neither statement can be made about the current system.

Why not use 105 percent of these prevailing wages in setting salaries for nonimmigrant workers? In that way all concerned could be assured that wage levels would *never* be depressed by the use of nonimmigrant workers. Even at 100 percent of

the salary-survey wages, employers could argue that they were not paying below the prevailing levels (even though tapping into a foreign labor force might well, ultimately, depress wages generally).

The 65,000 Limit. The 1990 Immigration Act, for the first time, established a numerical limit on the approval of a set of nonimmigrant petitions, in this case for H-1B visas. Given a piece of legislation that generally was a disaster for American workers competing with foreign-born workers, this was a remark-able provision.

Now that there is some possibility that the limit actually will work to reduce the growth in the number of nonimmigrant workers, the immigration bar and their corporate allies are sure to seek to repeal or soften this provision (*Interpreter Releases* 1993:1438-39). These efforts should be resisted stoutly. If there is a prospect of reaching the ceiling, INS should allocate the limited number of petition approvals near the end of the fiscal year by granting them to employers offering the highest wages.

NONIMMIGRANT VISA POLICY OF THE UNITED STATES

CHARLES B. KEELY
GEORGETOWN UNIVERSITY

The use of nonimmigrant visas by foreigners to reside and work legally in the United States has burgeoned in the last decade. Further, the interconnections between nonimmigrant visas—including educational, training, and occupational categories—and permanent residence is widely noted, the object of criticism, and a topic of recent legislative initiatives in the Senate.

The objectives of this analysis are to provide: (1) perspectives about the history, interconnections, and implications of current nonimmigrant visa policy; (2) criteria for developing nonimmigrant visa policy for contemporary realities, and (3) an outline of a nonimmigrant policy.[1]

Perspectives on Nonimmigrant Visa Policy

The interrelations between nonimmigrant and immigrant visas. It is easy to forget that current views about nonimmigrant visa policy and practice were not always the conventional wisdom. For example, during discussions of the 1965 amendments to the Immigration and Nationality Act of 1952 (the McCarran-Walter Act), the connections between educational and labor-related nonimmigrant visas on the one hand and permanent immigration on the other was not a major issue. The concept that nonimmigrant and immigrant visas for occupational skills

[1] This paper focuses on temporary visa categories that permit a visa holder legally to reside and work in the U.S. and on categories connected with formal education and training. Visitor visa holders (tourists) are not discussed.

should be seen as a whole, rather than two separate spheres of activity, was not part of the discussion thirty years ago. This is not such a surprise. The level of globalization of the economy and of firms[2] and the extent of international labor markets were in their infancy compared to today. In addition, temporary labor in the mid-1960s still meant unskilled, primarily agricultural labor. The U.S. ended the *Bracero* Program in 1964. In that context, temporary laborers hardly conjured up images of managers developing overseas markets for new products or researchers for communication technology.

When the 1965 Act replaced national origins with the visa preferences as the dominant selection criteria, little thought was given to the interconnections among student visas, exchange visitor visas, labor-related nonimmigrant visas, and immigrant visas based on occupational skills. That is not to say that absolutely no connections were noted. For example, a two-year return requirement was mandated for J-visa holders in order to avoid distorting the intent of exchange programs to train professionals in the context of development aid. In addition, the extent of adjustment cases among legal immigrants became a matter of comment, as if in some way adjustment, as opposed to first-time entry, was a perverse way to become an immigrant to the United States. In fact, in the past it was necessary for some immigrant visa recipients to leave the U.S. and travel to another country to pick up a visa and then go through the fiction of entering the country as a "new entrant" (and not a visa adjuster).

Now, when it is commonplace to note the interconnections between nonimmigrant

[2] In the 1960s, the focus was on multinational, rather than global, firms. The distinction is between a multinational firm still anchored in the country of its founding, but with operations in a variety of countries (e.g., Swiss Nestle, American Ford, German Siemans, Dutch Phillips, Canadian Seagrams) and a global firm in which the founding country connection becomes more and more tenuous. The decisions on investments, assets, accounting, and so on are made in a way the laws of the country mandate as a condition of business. A global firm is the logical outcome economically of multinational operations. An example of the problem of determining whether a firm is one or the other is reflected in the difficulty in deciding what is an "American" automobile if content is the criterion. Most examples of what were considered multinational firms would now be seen as global firms.

and immigrant visa categories, the odor of corruption attached to visa adjustment persists. The implication is that it is not right if the proportion of adjustments versus new entries is "too high." The justification for this bias is not articulated, but the transformation of a statistic into a substantive conclusion about the national interest persists, even among informed and intelligent observers.

Another instance of noting the connections between nonimmigrant and immigrant visas was in the context of "brain drain" discussions.[3] The main focus was on the recruitment of highly-skilled immigrants, but it was sometimes noted that the recruitment often took place among foreign students trained in developed countries rather than recruitment of advanced professionals in their own country.[4]

Despite instances of making connections between nonimmigrant and immigrant policy, the linkages had little practical impact on policy development in the period immediately following the end of the national origins quota system and the emergence of the preference system as the dominant mechanism for immigrant visa distribution.

Labor certification, the adversarial model, and the growth of the organized immigration bar. The 1965 Immigration Act had a profound effect on judgements about the consequences for the American labor force of immigration based on occupational skills. The 1965 Act changed labor certification from a passive to an active program. Under the 1952 Immigration and Nationality Act, persons admitted under a labor preference from an oversubscribed country were subject to review by the Secretary of Labor only if there was a complaint or if a single employer petitioned for twenty-five or more visa applicants. In high-quota countries like

---

3 Brain drain rhetoric persists even though internationalist arguments have all but prevailed among economists. The idea that change of immigration policies in developed countries could appreciably affect the labor force development policies of developing countries, much less affect economic performance in any but the most marginal and indirect way, has gone the way of doctrines about centrally planned economies.

4 It is somewhat ironic that the phrase "brain drain" originally was used to describe the United Kingdom post-World War II loss of physicians and other professionals to the U.S.

the United Kingdom, Ireland, and Germany, no review was necessary because there was no need to have recourse to the preference system to gain access to easily available visas. In short, in the very few cases where the preference system even came into play in oversubscribed countries, an occupational preference applicant could enter unless the Secretary of Labor took affirmative steps to prevent entry on the basis of a complaint or the large level of petitioning by a single employer.[5]

Under the 1965 amendments to immigration law, the emphasis of labor certification changed as the preference system became the dominant selection mechanism. A petitioner for a labor-related preference and all nonpreference applicants, including all Western Hemisphere applicants who were not the spouse or minor child of a citizen or legal permanent resident alien, could not receive a visa unless the Secretary of Labor approved via the labor certification process. The support of organized labor for immigration reform leading to the 1965 Act was obtained by inclusion of a labor certification process that required approval by the Secretary of Labor before a visa could be issued for any nonfamily immigrant visa. The labor certification process introduced in the 1965 Act institutionalized anxiety about the impact of immigration on the labor force. Dimensions of the economy were pitted against one another in an adversarial way, as if labor force development is a zero sum game. Any help to meet employers' felt needs was presumed to be achievable, albeit usually at the expense of U.S. workers. However, this anxiety was focused only on immigrant visas and did not extend to nonimmigrant visa practices.

[5] Recall that the preference system hardly affected the vast majority of immigrants under the national origins quota system maintained in the 1952 McCarran-Walter Act. Under that law, the overwhelmingly dominant criterion for admission to the United States was place of birth. All else paled in comparison to the importance of national origin for an American immigrant visa. Continued assertions that the 1965 Act changed the emphasis from occupational criteria to family criteria in the preference system are beside the point and mislead. National origins so dominated choice of immigrants that the preference system had virtually no impact on the selection of immigrants under the McCarran-Walter Act. To note the change in the preference systems of 1952 and 1965 is formally correct but irrelevant for the practical effect on policy outcomes.

One result of this innovation was the expansion of the organized immigration bar. Labor certification cemented the practices surrounding labor-related migration into an adversarial relationship. The role of lawyers in immigration proceedings grew tremendously, initially around administrative processes related to labor certification. The organized bar led the charge to introduce the L visa (intracompany transferees) in 1970 as a "noncontroversial amendment" to deal with the virtually undisputed needs of multinational corporations to engage in management trainee programs, management internationalization, and so on in order to open new markets. The rhetoric reflected a view that these were cases of "real" need. These were serious corporations that did not throw money away frivolously on international moves of key personnel. They were not sleazy schemers trying to circumvent the intent of the law and hurt American workers. In effect, the justifications of the purported need for L visas reinforced the perception of a need for strong vigilance about labor-related visas.[6]

The immigration process was progressively captured by the legal profession. In addition, corporations, educational and nonprofit research institutions, and other organizations developed trade associations regarding international personnel. No longer was immigration to the United States a matter of filling out forms and producing documents to prove marriage, educational achievement, or other bases for petitioner status. Not just employers, but private voluntary agencies increasingly provided legal services as a basic need of their clients to navigate an adversarial bureaucracy. Refugee admissions likewise became en- meshed in the culture of the legal profession. Lawyers are deemed a virtual necessity in presenting an asylum petition.

The adversarial process, dominated by attorneys on both sides, is now so ingrained that it is virtually naive to suggest that it could be otherwise. Perhaps it cannot, given what we have done in the last three decades. But it was not always so. Despite the jokes, there is, of course,

[6] Immigration law prescribes that the consular officer must presume all applicants for visas, including visitor or other temporary visas, are actually intending immigrants. The next step to a presumption that all petitions and statements, whether made by a U.S. citizen sponsor or an alien applicant, are fraudulent is not such a huge step.

nothing wrong with lawyers, *per se*. On the other hand, it is not an unalloyed benefit to transform civic interactions and citizens' petitions into legal battles, with the culture of the adversarial system dictating procedures and behavior.

The presumption of labor self-sufficiency. Like it or not, the assumptions surrounding immigrant and nonimmigrant petitioning for labor-related entrants are that applicants and employer sponsors are suspect. Even if honest, their petitions remain questionable because of a presumed harm of immigration based on labor skills to the U.S. labor force in general and to vulnerable American workers in particular. A presumption persists that a country, particularly a populous country like the United States, is or should be self-sufficient in regard to labor. The assumption of labor autarky is compounded by a view of the labor force as static, a fixed pie. Immigrants presumably take places that Americans can, or should be able to, fill if only employers would do their part to recruit properly and to create opportunity. Questioning these assumptions is suspect as self-serving propaganda on behalf of employers. To suggest that immigrant workers may produce jobs is sometimes judged, in the most charitable phrasing, as wishful thinking. But clearly, foreigners who install and train American workers on the use and maintenance of advanced knitting machinery, for example, maintain jobs in clothes manufacturing. An American equivalent is U.S. personnel of advanced aircraft residing temporarily overseas to train others in maintenance of American jet aircraft. If General Motors [GM] sponsors twenty-five German engineers / designers to assist in product development for the German auto market, those immigrant workers may help produce many American jobs to manufacture components for cars destined for the German market with its particularly stringent performance demands about cars. Is it good policy to say that such migration takes jobs from American engineers / auto designers and should be prohibited or should the focus be on the particular talents and familiarity with the demanding criteria of German auto buy-

ers and the potential for U.S. exports if GM autos command more of the German market?

It is difficult to adjust uninformed perspectives on the issues of job creation, export development, and other aspects of economic policy and their relation to international labor recruitment. Even if a more balanced perspective received some attention, difficulties would persist in changing viewpoints now so deeply ingrained in public policy, in the legal practice of an organized immigration bar in the public and private sector, and in policy rhetoric.

Regulating international migration, subsidies, and free trade in services. Government regulation of markets often results in subsidization of segments of a society. Tariff and nontariff barriers to protect domestic firms are obvious examples. Inefficient, as well as nascent, industries are protected from foreign competition. Even though free trade is a generally accepted principle, the mention of protection for nascent industry indicates that free trade is not an absolute principle.

Regulating immigration and the access of foreign labor also is justified as a protection of a domestic market: labor. Regulating international migration has the economic effect of subsidizing domestic labor. To note this does not lead to a conclusion that, by analogy to free trade, limiting immigration is undesirable. People are not goods and their entry into a society as actors is quite different than importing shoes, vegetables, or automobiles. Freer mobility of labor is politically unacceptable and justifiably so if a government is to protect vulnerable segments of the labor force. Adjustment to freer trade (as for example in reaction to NAFTA in all three signatory countries) is often costly, even brutal, for affected workers. Freer movement of labor would be more so, especially for the least adaptable and less skilled. Free movement of labor has been agreed to and endured only in the context of economic agreements between economically advanced countries of relative economic parity (specifically in the EC/EU and the Nordic countries). Free labor movement provisions in economic agreements among less developed countries either have not been implemented or have been abandoned. To note the political im-

practicality of free labor movement or the persuasive arguments against such a policy, except in special circumstances, does not negate the fact that it supplies a subsidy to domestic labor.

The issue of labor mobility becomes complicated when the topic of trade in services is discussed. Trade in services often requires the presence of a person to provide the service, whether high-level management consultation, artistic performance, or on-site installation and training for specialized equipment. There are other services that are more flexible regarding performance sites. Take as an example a simple and relatively unskilled service function: data entry. The service can be performed by American workers in the U.S. The function can be performed by imported workers in the U.S. The service can be exported to a foreign country to be performed by foreign workers in their own country and the transformed data electronically transported to the U.S., bypassing even the importation of a data tape or other physical product containing the transformed knowledge resulting from data entry.

It is a small leap to the example of computer programming that has been not only a thorn for nonimmigrant policy and practice, but also a controversial topic for U.S.-based firms regarding employment practice.[7] When Seatrain Corporation moved programming operations to India, U.S. workers lost jobs. Intel justifies movement of some programming operations overseas as a way to allow U.S. workers

[7] An important aspect of the controversy about computer programmers entering the U.S., especially on H1-B visas, is the spreading practice in the American economy of contracting out. Like leasing of equipment, contracting out reduces investment costs and allows for flexibility regarding labor costs. Workers need not be added to the payroll. Lesser skilled workers do not benefit from spread effects of the more costly salaries and benefits that large firms, which have a spectrum of skills in their work force, usually pay. A janitor in an IBM facility, for example, benefits from the spillover of IBM practices in ways not available to a counterpart in a janitorial company that employs primarily unskilled workers. Contracting out exists independently of immigration. Methods to lower labor costs, which is another way of saying recruitment of cheap labor, is not confined to importing labor. Combining contracting out and foreign labor may maximize labor cost cutting. To block low-wage labor importation, however, will not end or counter the independent effects of contracting out for goods, equipment, or services.

to engage in the cutting-edge development that requires their advanced skills and justifies their higher pay in a globally competitive environment. The savings in routine programming, the company argues, allows investment in the more expensive R&D work by American workers. If a company wins a contract to develop customized programming services and uses B visa workers to perform programming routine tasks, is that an abuse or a creative use of existing law to meet an unanticipated situation that combines the elements of contracting out and knowledge-based services? Is it any more of an abuse than the less controversial increased use by foreign-based corporations of E visas for intracompany transferees, a visa category with distinct advantages over the L visa for the firm (but not necessarily for the employees and their family)? Whatever one's opinion about what policy should be in such situations, an honest answer would acknowledge that the law and policy did not anticipate the business situation or the business response that combined the general move to subcontracting and the importation of short-term labor to supply a knowledge-based service.

Regardless of one's opinion about profit versus greed, obligations to shareholders versus obligations to fellow citizens and the country that provides the opportunities to prosper as a firm, the complications for immigration policy introduced by the relation between trade in knowledge-based services and migration, especially when combined with contracting rather than staff expansion, are real. There is no simple solution that maximizes trade in services with virtually no migration. Conversely, open migration will not translate into maintaining a competitive technological edge. A one-size-fits-all policy on temporary labor is an anachronism that ignores the reality of contemporary economics and the process of wealth production and job creation in knowledge-based industries.

High-tech economies, increasing returns and international migration. Dominant economic thinking assumes diminishing returns. The ideas about investment and the creation of wealth were developed at a time when agriculture, extraction of resources, and bulk-manufacture dominated the economy. Diminishing returns meant that the more you did something,

the harder it became and the less rewarding it got. As coal was extracted, for example, it became harder to find and take out good coal. As coal became more expensive, hydroelectric became competitive. Coal and hydroelectric competed for shares of the energy market. In such a situation, economic theory and methods predicted an equilibrium and the relative prices of competing energy sources. There is one equilibrium solution until another energy source is found or until the law of diminishing returns leads to one source being so expensive that it commands no market share.

At that point, a new equilibrium is needed. The context is changed. High-tech economies are driven more by "congealed knowledge" than by "congealed resources." High-tech products include pharmaceuticals, telecommunications, computer software, aircraft, and electronics. In these high-tech economies the main costs are up front. The cost of pro-duction per unit becomes cheaper as volume increases, not more expensive. The first version of Windows 95 cost perhaps about one-half billion dollars. The second cost about twenty dollars for the disk, the manual, and the packaging. The more units of Windows 95 that Microsoft sells, the more it can make per unit. This is an example of increasing, rather than diminishing, returns.[8]

A characteristic of knowledge-based industries is that they enjoy protection for the conversion of their knowledge creations in copyright and patent law and policy. In addition, in these industries, history counts. The first to achieve a discovery often sets a standard that results in other technologies not being pursued or adopted. First discovery or first invention gives a tremendous market advantage. A discovery, if registered, gets some protection that allows bringing a product to market. If that product sets a standard, the return is even greater.

[8] Economists trying to develop theory and methods to deal with assumptions of increasing returns and the possibility of more than a single equilibrium solution are dealing, in technical jargon, in dynamic stochastic discrete choice models, sometimes more simply referred to as path dependent models. The discussion in this section relies on a profile of one of the principal economists (Arthur 1994a; 1994b) in this area.

Microsoft's advantage with the DOS operating system for computers and the return to the developers of the VHS format that bested the Beta format for home video are clear. Recently, developers of competing standards for compact disks agreed to a common standard that allowed them all to participate in the rewards of a single format for CDs to carry audio, data, and video content.[9]

While the first to market will not necessarily set the standard and reap the rewards of increasing returns, being first provides an advantage. Many examples illustrate that becoming a standard gives tremendous market advantage, if not monopoly. Video tape format and computer operating systems, already noted, are two often-cited examples. Once a standard is adopted, other technology, inherently as good, goes undeveloped, often forever or until its benefit for some other task becomes clear. The adoption of the internal combustion over the steam engine is an example of the neglect of one technology, steam, because another became the standard. Sequential processing rather than parallel processing continues to dominate in commercially produced computers, although advantages of parallel processing for some complicated tasks has led to renewed interest in that technology.[10]

For knowledge-based industries, time is of the essence. Both technology development and product development have an important element of timeliness to them, along with the job creation, export growth, and other consequences of standard setting in a product area if the financial rewards are to be reaped. In those environments, personnel recruitment for R&D, product design, international marketing, and so on do not operate on an assumption that labor is to a large extent substitutable.

---

[9] Ironically, the VHS will decline and eventually go the way of 78 rpm phonograph records to be replaced by the disk, smaller than the old Beta video disks and not exactly the same technology, but a disk nonetheless. Note also that the triumph of the disk means that digital tapes for audio reproduction will not be widely marketed.

[10] The pioneer ENIAC computer was a parallel processing machine.

Arguments about immigration and labor often operate at a level similar to the development of classical economics in which a worker was a worker and in most cases substitutions were available. This undergirded the assumption that most countries, and especially those with large populations, were and could be labor self-sufficient, except in extraordinary circumstances like total mobilization for war. Thus, in the United States, when Turner published his thesis about the closing of the frontier, arguments for immigrants to fill up the land diminished. When industrial unemployment appeared, the need of immigrant labor was disputed. Contemporary proponents of immigration reduction point to the difference between today and the heyday of immigration into the United States. The labor needs of a postindustrial economy, where intellectual skills are more important, differ from an economy in which agriculture, infrastructure building, and heavy manufacturing dominate and labor is more readily substitutable.

The notion that labor self-sufficiency can be presumed for an economy, particularly one characterized by a heavy reliance on knowledge-based sectors, is questionable. A postindustrial economy needs few or no foreign unskilled and lower-skilled workers. That does not preclude a need for those with very high skills or specialized experience. Quick access to advanced human capital is important for timely development of technology, given the protection of patents and copyright, as well as the relative advantage of early entry into the market for products with competing standards. Similarly, effective marketing in different cultures requires collaboration of international personnel who know various markets and the product line. Perhaps it is necessary to rethink what we mean by labor and our notions about how the economy returns profit on investment, creates jobs, and gets access to personnel. To dismiss calls for migration policy and law that responds to international labor markets as simply the desire of corporations for cheap, even if highly-skilled labor, may be a mistake.

U.S. higher education as service export industry and its relation to immigration. The American college and university system is a valuable service export that has downstream spinoffs as alumni/ae of U.S. schools move into responsible positions in the private and public sectors of their societies. More immediately, college and especially postbaccalaureate degree holders provide a supply of potential immigrants based on the advanced or scarce skills that they acquire.

The acceptability of linking international educational programs and nonimmigrant and immigrant policy is questioned for three reasons. First, the objective of providing education in a context of aid for development conflicts with allowing adjustment from a student visa status to a nonimmigrant or immigrant status based on skills. The view makes little distinction between students sponsored by their governments, international organizations, or U.S. scholarship programs aimed at skills for development and independently financed students, even from advanced countries.[11] Second, a cloud hangs over all adjustments of status, as if they pervert the migration system or indicate devious intentions. Third, the assumption of labor self-sufficiency leads to questioning why U.S. students are not in the programs that lead to skill qualifications for nonimmigrant or immigrant status. U.S. educational capacity seems to feed a supply-side process. Educational programs cater to foreign students (and may not be otherwise viable). The availability of these students to industry leads to reliance on recruiting foreign students, with the justification that Americans with the requisite skills are unavailable.

While educational programs that enroll high proportions of foreign students can be self-serving for both the universities involved and employers, that is not nec-

[11] Proposals have been made requiring foreign students to return home for one to three years, making no distinction on source of funding. Pending legislation has dropped a return requirement.

essarily the case.[12] Recourse to foreign graduates is not inherently negative. There is no *a priori* reason to apologize for seeing foreign graduates as a pool for the United States of potential immigrants or temporary workers with very high skills. What perhaps is needed in regard to nonimmigrant and immigrant visa programs is a balance between control and facilitation mentalities. Disturbing development aid goals makes no sense, for example, but neither does a requirement that a foreign degree holder from an American university leave the country for three to five years in order to eliminate their recruitment as nonimmigrant workers or immigrants. Such a policy overlooks other benefits, long- and short-term, of an active education export sector for the U.S. economy and international relations.

Conclusion. These disparate comments about the history, characteristics, and assumptions that accompany discussion of

[12] Some of the characterizations of higher education in the debate over foreign students and immigration have the flavor of the criticisms leveled at private voluntary organizations [PVOs] in the refugee field in the early 1980s. PVOs often performed resettlement services for the federal government when people were admitted as parolees and before any Congressional authorizations to pay for those services. In effect, the private sector advanced money with no guarantee of repayment in every case. When some PVOs developed contingency funds through savings from prior grants, they were accused of being "Refugee, Inc.," as if PVOs and their parent organizations were getting fat at the public trough. The university in western tradition has always being internationalist. Scholars were and are recruited for talent, regardless of nationality. The most cursory overview of American experience, especially in this century, confirms the continuation of that tradition. It has been beneficial for basic national defense and the economy. Similarly, students have been international. The University of Paris student body in the Middle Ages was organized by "nationes," broad groupings by area of Europe from which they came. Foreign students attend U.S. universities for many reasons besides development-related aid programs and many are not sponsored by government or multilateral organizations. To equate foreign student training with a new-found way for higher education to be self-serving is historically ignorant. A better case has to be made than mere notation of a correlation of foreign students in universities and recruitment by corporations to hand down an indictment of U.S. higher education. To prohibit recruitment of superstar engineering students from elite graduate schools by Raytheon or Motorola for advanced communications technology research as a way to counter degree mills in the private sector specializing in elementary computer programming or cosmetology is myopic. In the name of the national interest, such policy opposes the nation's true interests.

nonimmigrant visas do not command universal assent. They are presented to stimulate discussion and to question many of the assumptions and much of the conventional wisdom surrounding nonimmigrant visa policy discussions that pass for facts. As a result, these observations do not translate effortlessly into a nonimmigrant worker policy. They provide guides for criteria to sustain a nonimmigrant policy that recognizes that competing interests cannot be simultaneously met and that the structure and operation of the economy and labor force have changed and continue to develop. The next section outlines criteria to use in the development and evaluation of proposed nonimmigrant visa policy for occupationally-related reasons.

Criteria for Developing a Nonimmigrant Visa Policy

Acknowledge competing interests and conflicting values. International recruitment of labor may have differential impacts on different parts of the U.S. economy and even on different segments of the labor force. General Motors recruitment of German engineers/auto designers can be used as an example. Suppose that the request to recruit twenty-five Germans was denied and that GM went ahead with product development to increase German market share with U.S. engineers. In that case twenty-five "American" jobs were saved. Suppose, however, that the result of that product development was lower penetration of the German market than would have taken place if the German personnel were allowed into the U.S. and that, as a result, 400 U.S.-based jobs were not created to manufacture components for cars destined for German retail. There are competing interests between 25 engineering jobs and 400 manufacturing jobs, as well as lower U.S. exports, lower reputation for U.S. products as well engineered in the important German market, and lower profit for GM. Any policy on international personnel and the immigration system must acknowledge that such trade-offs are inherent in such a system, that judgement is required, that solutions cannot always be legislated in advance.

Decision-making processes authorized in legislation, however, can tip the balance regarding which interests and values are likely to be favored. Quite simply, export promotion might be favored if "international personnel recruitment" decisions were in the Commerce Department rather than protecting American jobs by "labor certification" decisions remaining in the Labor Department. Note how even the phrases in quotation marks in the previous sentence put a different spin on a decision whether to permit issuance of an immigrant or nonimmigrant visa based on occupational skills. To pretend that no one will be advantaged or hurt by how the process is organized or what decisions are made is wrong-headed. There will be winners and losers regardless of the proposals made or the policy finally adopted and implemented in legislation and regulation. Those winners and losers are not confined to capital versus labor. In the GM engineer example, the creation of 400 manufacturing jobs is sacrificed for 25 higher-skilled, probably nonunion, higher-payed, and most likely less-disadvantaged U.S. college graduates. Deflecting foreigners from the labor force is not as clear-cut as sometimes presented.

Set labor-related migration to meet domestic goals as the context for nonimmigrant visa policy and integrate policy for visa categories within the nonimmigrant domain and between immigrant and nonimmigrant categories. The criterion of recognizing and addressing interrelations is founded on the contention that all immigrant and nonimmigrant admissions for labor force reasons ought to be included in a unified policy. The controlling reality is labor force recruitment and insertion, not administrative and legal distinctions between visa categories and immigration statuses. The recent growth in the use of nonimmigrant visas and the underutilization of occupationally-based immigrant visas under IMMACT 90 legislation indicate that recruitment behavior by the private sector and legislative assumptions vary. Legal distinctions drawn for administrative and legislative purposes have been regarded as set in concrete. The adver-sarial process ingrained in immigration practice has not resulted in a cooperative and collaborative fashioning of legislation in which government, employers, and labor contribute. Collaboration does not imply agreement on all issues. But policy based on assump-

tions made by Members of Congress, their staffs, and nonbusiness "experts" does not guide international labor recruitment practices. The result of the adversarial process is that employers and their lawyers analyze legislation and devise ways to use it or to get around it to meet their objectives. This is done not just by marginal employers. This is mainstream practice; everybody ivolved in immigration policy knows it.

What ought to guide policy development is the need of the economy for both timely availability of certain skills and for protection of U.S. workers. Those needs can be translated into various mechanisms for permitting recruitment of noncitizens, when appropriate, in nonimmigrant and immigrant statuses, including adjustment of status. The movement from one status to another ought to be based on meeting labor force goals —including labor protection—not on an arbitrary concept about the propriety of adjustment of status by foreign students, intracompany transferees, or any other nonimmigrant or immigrant. Even so radical a departure from current practice as requiring work experience under a nonimmigrant visa as a condition for obtaining a labor-related immigrant visa ought not to be rejected on principle.

The unbundling of family and employment visa preferences in the 1990 Immigration Act eases the process of tackling skills-based entry in its entirety as the domain to be addressed. The configuration of immigrant and nonimmigrant statuses based on skills becomes a tool to achieve goals, not separate domains in which the immigration status dominates the labor force goals.

Regard adjustment of status as an opportunity, rather than as a restraint. The design of a labor-related program ought not to try to minimize (nor maximize) adjustment of status. The capacity to adjust ought to be seen as neutral in itself and used to the extent that it may further the policy goals of accessing foreign labor at minimal harm to U.S. workers. Adjustment from a student, training, or exchange visa ought not to be excluded outright. Particular conditions may attach to some student visa holders, depending on their

sponsorship, for example. Entire visa classes as currently configured should not be excluded.

Distinguish between knowledge-based workers performing nonroutine tasks that result in otherwise unavailable goods (products, exports, technology, scientific knowledge, etc.) and other workers. If the concepts of increasing returns and congealed knowledge make sense, then workers who perform nonroutine knowledge-based services merit particular attention. Current immigration policy acknowledges the exceptional worker and people of world-class talent. A computer programmer of exceptional creativity demonstrated by prior output and reputation is not a run-of-the-mill programmer with a B.S. degree. The latter ought not be allowed into the U.S. on nonimmigrant or immigrant visas to compete with competent U.S. programmers. To be sure programming, even of routine kinds, is no mean skill, but it is widely available in this country. A superstar, however, may merit a visa. Similarly, the United States has many trained chefs and there is no reason to recruit even specialty chefs for a particular cuisine. Trained chefs can receive the additional training to perform tasks for whatever cuisine is desired. This does not preclude the truly world-class chef from occasionally receiving a visa.

One can multiply examples. The criterion should be clear. Knowledge-based services of a nonroutine nature ought to result in visas. By implication, routine, knowledge-based services and personal services should not command U.S. immigrant and nonimmigrant visas, except in the rarest cases of truly world-class practitioners.

View higher education as a labor resource. If the policy focus is on labor force needs and both nonimmigrant and immigrant visas are seen as instruments to achieve policy goals, then the service export sector of higher education ought to be seen as a resource. It is counterproductive to adopt an arbitrary policy that any foreign student ought to be required to return to her or his own country. It makes no sense to erect barriers to entry into the U.S. labor force for any foreign student graduate of a U.S. university that are greater than for a foreign graduate of

a foreign degree program. All foreign students are not enrolled in U.S. educational institutions for economic development goals. All foreign students are not supported by government scholarships. If there are problems or abuses in visa adjustment from a student or training visa, the solution is not wholesale discrimination against foreign students. Permitting adjustment does not imply a right to adjustment or the suppression of such other goals as protection of domestic labor.

Do not rely on immigrant and nonimmigrant visas for labor-related migration as a revenue-generating scheme. The concept of imposing a tax on applicants or sponsors for labor-related visas is government extortion. If the Commission or the Congress thinks that a visa for labor-related migration is detrimental, it should not make it available to those that can afford an official bribe. To pretend that such funds are needed to underwrite training or retraining programs by the federal government, after years and billions of dollars on training, is a sham. The problem of Black youth unemployment, for example, has not been lack of funds for youth training. Similarly, a pot of money funded by a fee for a labor visa will hardly translate into higher enrollment of disadvantaged American youth in nursing programs. To implicitly promise such results from a fee for a labor visa is disingenuous. Further, in proposed legislation the Department of Labor has unfettered discretion over the use of such funds for DOL programs, including for example, summer jobs programs. As worthy as summer jobs programs may be, their connection to a fee for labor visas as a means to reduce reliance on foreign labor or to increase domestic preparation for high-skilled jobs is charitably described as a stretch.

International Labor Migration Policy Outline

A design for nonimmigrant visa policy ought to be couched in the wider idea of a policy for controlled recruitment of needed and useful noncitizen labor that does not harm the domestic labor force. The “do no harm” injunction has to be understood in a way that allows for some cases of adjustment in the U.S. labor force. However, displaced workers must be

placed in equivalent paying jobs with all relocation costs paid and new jobs must result if the visa is to be granted.

A characteristic of labor visa policy ought to be a continuation of labor certification to assess that the foreign workers are complementary or, if replacements, that they nevertheless produce more jobs because of the special skills of the incumbents and that displaced workers get new, equivalent jobs. Certification should continue to ascertain that wages and standards are not undercut.

A new balance must be struck between labor force protection and enhancement of the economy through judicious recruitment and use of noncitizen labor. If decisionmakers are incapable of accepting that no country on the cutting edge of competitive, high-tech industry is labor self-sufficient, then this set of presentations will fall on deaf ears. If decisionmakers think it impossible to design regulations that distinguish among workers and their capacity to create jobs or reject the idea that all workers are not equal in their contribution to job creation, wealth production, or potential contributions, then a one-size-fits-all policy should be adopted that fundamentally limits all labor migration to a minimum.

Confine restriction of adjustment of status to achieving articulated goals. Conversely, permit adjustment of status within nonimmigrant categories and to immigrant categories, unless a specific goal dictates otherwise. For example, require students, trainees, or exchange visitors sponsored by their own government, the United States, or multilateral organizations and agencies (e.g., UN agency scholarships or fellowships) with funds meant to develop skills for development to provide evidence of work in their home country for a number of years before becoming eligible for adjustment of status to a work-related immigrant visa.

Eliminate distinctions in nonimmigrant visas for intracorporate transfer between U.S.-based and foreign companies. This may require analysis of trade and investment treaties to renegotiate provisions conforming to the realities of global firms. Broader international discussion of this issue may be needed in multilateral and even nongovernmental forums to develop

common understandings and practices about international migration in the contemporary world.

Limit an immigrant visa for occupational skills to persons whose skills are unavailable in the United States, or who have a demonstrable level of attainment that is recognized as world class, or who have a combination of skills and experiences and a connection to a corporation that justifies working in the U.S. as part of a career advancement that is a normal business practice. Do not impose fees on the immigrant or sponsor. No specific recommendation regarding annual allotments is made.

Require nonimmigrant labor visa applicants to demonstrate competence or experience unavailable in the United States or involvement in normal corporate career development for intracompany transferees who have a connection with the company for a year or more. Allow sponsoring institutions training and exchange visas for promising talents, demonstrated by scholastic records, letters of established referees, and ordinary review procedures by the sponsoring institution. Competitively chosen Postdoctoral fellows are an example.

Do not bar nonimmigrant visa holders who develop a level of expertise to qualify for an immigrant visa from adjustment by the mere fact of their having held a nonimmigrant visa.

Evaluate the time limits on nonimmigrant, labor-related visas by analysis of industry practice, the history of prior nonimmigrant, labor-related visa holders (what proportion adjusted to permanent resident, went to a non-U.S. position in the corporate sponsor, etc.), and practice by other countries. The issue of time limits requires attention not only to length, but also to renewals and recertification.

In concert with other countries, move to a policy that permits an accompanying spouse a work permit in the United States. Spousal work prohibitions are anachronistic and, given current realities, more often than not sexist in their impact.

Have one immigrant visa category for occupationally-related applicants in a labor-related visa package that incorporates nonimmigrant and immigrant visas. This would require sponsorship by the employer and labor certification about availability or the world-class credentials and prevailing wage and conditions issues as is done currently. Nonimmigrant visas would have:

1. **Students**, perhaps divided into (a) government or multilateral agency sponsorship as a development program and, therefore, a limit on adjustment and (b) nonsponsored;

2. **Exchange visitors**, again with an (a) and a (b) category for governmental, development-oriented sponsorship related to adjustment;

3. I**ntracompany tranferees**, eliminating the current distinction involved in L and E visas;

4. **Temporary visitors for business**, the current B visa, with a prohibition against performing work as part of a joint venture or subcontract except to manage the joint venture or job for the B visa period; and

5. **Distinguished workers who are eligible for an immigrant visa but do not wish or require one** (similar to the current H visa holder who may be recruited by a new employer but have a limited-time horizon for work in the United States).

No changes are proposed in the current arrangements for performers and professional athletes, news media, representatives of international organizations, and so on. No limits ought to be imposed for nonimmigrant visas at the outset, but levels ought to be monitored and Congress encouraged to review and evaluate trends.

The general thrust of these proposals is that nonimmigrant visas be available for recruiting world class people to take up a new position in the U.S., for intra-corporate transfers by current staff, for education and training, and for short-term business trips. Education, experience, and training in the United States may qualify

a person for an immigrant visa and high attainment should qualify a person to become a permanent resident. Conversely, people with skills that can be reproduced easily or that are available in the U.S. should not be given visas. The labor force is protected by the retention of certification regarding availability, qualifications, and labor standards.

The attempt in this review and recommendations is to balance reasonable need and reasonable protection under current circumstances that include international recruitment as a normal and necessary aspect of international competitiveness. The United States should expect and demand reciprocal access from other countries. Access to the U.S. labor force should be limited to those whose skills are in short supply, who produce jobs, exports, and advances in the growth sectors of the economy in knowledge-based industry, and whose entry is useful because of reciprocal obligations regarding multinational corporations and keeping U.S. companies competi-tive. This view accepts the role of education and training as integral to knowledge-based industrial growth and competitiveness. At the same time, current procedures to protect the U.S. labor force should remain in place. People who would receive visas under these proposals not only would not harm the American labor force but would energize job creation through discovery and product development and opening of new markets to American goods and services.

THE NEW HIGH-TECH BRACEROS? WHO IS THE EMPLOYER? WHAT IS THE PROBLEM?[1]

MICHAEL P. SMITH
UNIVERSITY OF CALIFORNIA, DAVIS

The California economy is undergoing basic changes as a result of rapid downsizing in the U.S. defense industry, a global corporate trend to restructure operations and become more flexible, the deployment of manufacturing and processing functions of the state's highly vaunted high-tech industry to other states and nations with weaker regu-latory environments, a volatile economy, and growing job insecurity. These developments constitute a wider context helping to explain the anti-immigrant backlash now occurring in California and elsewhere. One facet of that backlash has been a call from diverse quarters, including environmental organizations, professional associations representing U.S. skilled workers, and grassroots anti-immigrant groups (see: Bellinger 1993:69-70; Carey 1993) for a reexamination of 1990 changes in U.S. immigration law [IMMACT] that increased the number of highly-skilled nonimmigrant workers that U.S. employers could hire for "temporary" periods of as many as six years under the H-1B visa provisions of current immigration law.

The political-economic trends now condensed under the rubric "global restructuring" (Feagin & Smith 1987:3-34; Dicken 1992) locally have produced an uneven, volatile, and fluctuating labor market demand for highly-skilled professional and technical workers in the California economy of the 1990s. Existing empiri-

[1] I wish to acknowledge the contribution of my research assistant, Marie Ciepiela, who coauthored the larger report on foreign worker specialty employment (Smith & Ciepiela 1995), parts of which were drawn upon in writing this paper.

cal studies are few and none have been drawn with sufficient detail or categorical occupational focus to map precisely the impact on the skilled labor markets in the state's economy of the use of nonimmigrant workers drawn from the global workforce. To be sure, a central issue of concern to workers and federal and state regulatory agencies in California is the possibility that the presence of highly-skilled foreign workers made available by current provisions of immigration law com-pounds an already unfavorable labor market for U.S. skilled workers. How well-founded is this concern? This study seeks to separate this question from the wider questions of job loss caused by such other processes as growing cor-porate downsizing, defense industry restructuring, and the overproduction of scientists and engineers by U.S. universities.

The claim has been made that the use of nonimmigrant workers is a cause of both job displacement and wage depression among U.S. skilled workers. How valid is this claim? How does the answer vary by type of skilled occupation? What has been the impact of the employment of nonimmigrant skilled workers in the sector of the California economy that has been most heavily reliant on the use of H-1B temporary skilled workers since 1990, namely, the computer industry in Silicon Valley? This research paper seeks to shed light on each of these key questions.

The paper is divided into four parts. The first section provides a contextual overview of the changing California economy. The second section details the study methods used in the larger qualitative research project from which this paper is drawn. The body of the paper then focuses on the central question raised in the title: "The New High-Tech *Braceros*? Who Is the Employer? What is the Problem?" Finally, to underline the importance of investigating broad questions, such as immigrant labor displacement on a case-by-case basis, selected comparative data are presented to show that other employment sectors, in this instance university teaching and research and the biotechnology sector, operate quite differently from the computer sector and offer quite different answers to the ques-tions at hand.

The Changing Economic Context of Reception

As the California economy plunged in the early 1990s, people and businesses began leaving the state in unprecedented numbers. According to the California State Department of Finance, 600,000 Californians left the state in the fiscal year ending June 30, l993. Every county in the state except San Francisco lost population. Two-thirds of the out migration occurred in the five-county Los Angeles metropolitan region, where defense cuts were most pronounced. Despite the declining economy and the overall out migration, 200,000 legal foreign immigrants entered California in the following fiscal year.

In Silicon Valley, the early 1990s was a period characterized by efforts by major employers in the computer industry to downsize, streamline, and outsource operations. According to industry analysts, this restructuring of operations was, in part, driven by the impact of defense cuts on the computer industry but also by such factors as: (1) the overall maturation of the industry; (2) a desire of firms to shift from the manufacture of mainframes to desktop computers; (3) the pressures of competition from new entrants into the global marketplace; and (4) an ensuing personal computer price war that cut deeply into profits. The chief labor market effect of these developments was to reduce opportunities for full-time employment in computer-related jobs in Silicon Valley.

An early strategy used by computer industry firms in the 1980s was to move low-wage manufacturing jobs offshore or to other states with weaker regulatory environments while retaining high-pay programming and engineering jobs for Silicon Valley. By the early 1990s, this approach was superseded by a newer computer industry strategy of relying more extensively in Silicon Valley itself on temporary employees, including foreign computer consultants, to perform an increasing number of project-specific operations. The downsizing of the permanent workforce resulting from these strategies allowed major computer manufacturers to shed thousands of permanent jobs in both Silicon Valley and worldwide. By the end of 1993, com-puter firms head-

quartered in Silicon Valley were able to cut between 15 and 25 percent of their permanent worldwide workforce while maintaining produc-tivity, although not always market share.

Silicon Valley's Santa Clara County was one of the worst hit parts of Northern California throughout the period. The county's employment in computers and office machinery plunged from 73,600 in 1990 to 43,000 in September 1994. The shakeup of the computer industry labor market in Silicon Valley continued throughout 1994 as a major new round of mergers and acquisitions enabled firms, particularly in database software and on-line services, to reduce workers and re-turn to profitability.

Paradoxically, industry analysts point out that the demand for software engineers in Silicon Valley was high throughout the downsizing period and continues to be high today. A recently released study by the public-private Joint Venture Silicon Valley Network points out that from 1989 through 1993, computer software engi-neering emerged as the region's biggest job generator (Sinton 1995). Software em-ployment in Santa Clara County actually grew by 9,556 jobs during this period, although this growth did not compensate for the loss of 17,332 defense-related jobs and 11,775 semiconductor hardware jobs during the same period. This appears to be a result not simply of the shift from hardware to software development, but also a reflection of consistently high de-mand for *temporary* software engineers, programmers, and coders as companies laid off full-time employees.

The decline of the defense sector has been a related factor contributing to the ero-sion of high-skill, high-wage jobs in Cali-fornia. Clearly, the state has taken the brunt of the nation's defense layoffs, suf-fering 25 percent of all jobs lost nationally in the defense sector (National Commis-sion for Economic Conversion and Disar-mament 1994). Although the three met-ropolitan labor markets studied in the larger research project from which this study is drawn—Silicon Valley, the San Francisco Bay area, and greater Los An-geles—have been affected by defense downsizing, major defense and aerospace related layoffs and plant closures have been especially severe in Los Angeles

because of the dependency of that region's economy on the military budget as a central engine of economic growth. Between 1989 and 1993, 240,000 jobs disappeared in Los Angeles county. The once seemingly recession-proof aerospace and electronics industries abruptly reversed course and the construction and real estate industries floundered with them. In 1993 alone, 110,000 high-wage, defense-related jobs were lost to the Los Angeles economy (Smith 1996).

The loss in California of highly-skilled jobs through federal government budget cuts, corporate downsizing, and consoli-dations and mergers in the defense, electronics, and computer industries was paralleled by a major belt-tightening of the University of California and state college systems. This university down-sizing was necessitated by cuts in state funding for higher education in the face of declining state government revenues produced by the prolonged recession. In California, the public university down-sizing policy was characterized by the introduction of incentives to encourage early retirement of tenured faculty members, increasing reliance on tem-porary lecturers to teach some vacated courses, the cancellation of other courses, and an increase in both class sizes and the time required for students to complete their course requirements.

Among the rare exceptions to the adverse employment trends in California during the early 1990s were the biotechnology and health services sectors. In these sectors, skilled research and service jobs increased throughout the period, even in Southern California.

Investigating Nonimmigrant Employment: Study Methods

In a comprehensive qualitative field research study, commissioned by the U.S. Department of Labor (Smith & Ciepiela 1995:1-57), I directed a study team that investigated the process and efficacy of the Alien Labor Certification Program and the Temporary Worker Visa Pro-grams used to bring foreign professionals into skilled labor markets in California. Our recently completed research focused on the computer software and hardware en-

gineering industries in Silicon Valley and on the biological and chemical industries, universities, and medical centers in the San Francisco Bay Area and greater Los Angeles. These locations and employment categories were chosen because, in the two years preceding our study, our selected sample of employers in these regional labor markets, including private firms, universities, and medical centers, were found to have the highest numbers of Labor Condition Appli-cations [LCAs], permanent labor certifi-cation applications, or both in the state of California. By this selection method, five skilled occupational sectors in California were found to rely heavily on foreign worker immigration programs in general and the H-1B visa category in particular. These included computer soft-ware and hardware engineering, elec-trical engineering, university teaching and research, biotechnology research and development, and medical research and services. Our larger qualitative ethno-graphic study generated substantial evi-dence concerning the nature and extent of job displacement by highly-skilled foreign workers in each of these occupa-tional sectors in California.

Qualitative and historical data for this study were gathered during 1994 and early 1995 primarily by conducting qualitative, open-ended interviews with all parties involved in the recruitment, employment, and regulation of foreign non-immigrant skilled workers. Ethno-graphic interviews also were conducted with samples of both U.S. and nonim-migrant skilled workers affected by this employment process. Our overall sample thus included: U.S. employers; foreign workers; U.S. workers; officials from the Regional Office of the U.S. Department of Labor [DOL] and the Immigration and Naturalization Service [INS]; immigra-tion attorneys; and representatives of professional associations and unions whose members were impacted by the process. Our study goal was to compile a balanced set of viewpoints enabling us to assess the impact of the 1990 IMMACT legislation on the business and personnel practices of U.S. firms, on the employ- ment opportunities of U.S. skilled workers, and on the selected U.S. labor markets during an ongoing period of global economic restructuring and economic recession and corporate and university downsizing in California.

Our study sample of *employers* included interviews with fifty-eight individuals representing thirty-seven employers in Northern and Southern California. These data were supplemented by twelve participant observation interviews conducted with all categories of employer at a two-day seminar in San Francisco sponsored by the American Council on International Personnel (1994) for employer immigration represen-tatives. Employers thus comprised the largest and most diverse segment of our sample. Among these, the computer industry, which forms the central focus of this paper, was the most extensively and intensively investigated. Our computer industry sample included thirty-nine individuals representing twenty-two computer and engineering firms and five computer consulting businesses.

To elicit the views of *immigration attorneys*, most of whom represented employers seeking nonimmigrant skilled workers, we interviewed ten attorneys in sessions lasting from one to two hours. We also attended several panels on H-1B visa issues at the annual meeting of the American Immigration Lawyers Asso-ciation held in San Francisco during the period of our study. Attorneys were asked to describe their experience with the 1990 IMMACT regulatory changes as well as their clients' needs for sponsoring foreign workers.

Our sample of *workers* included fifteen skilled U.S. workers and twelve foreign nonimmigrant skilled workers, one of whom represented an Indian professional association. Sixteen of these interviews were in-depth qualitative ethnographies of respondents' work histories and contemporary experiences in the globalized labor market. Eleven additional interviews were conducted by a combination of e-mail correspondence and telephone interviews with highly-skilled U.S. and foreign workers who are members of two computer user groups of highly-skilled workers.

To supplement the perspective of workers we interviewed six repre-sentatives of *professional associations and unions.* These respondents varied in terms of their organizations' active involvement in issues of immigration and labor market conditions for their con-stituencies. Two associa-

tions represent computer consultants and have been actively lobbying the DOL and the INS for more vigorous enforcement of IMMACT prevailing wage provisions and more rigorous determination of "shortage" occupations. The other four representatives of engineering trade associations and unions, while less directly involved in such questions, nevertheless provided insightful analyses of how changing structural conditions in the global economy have affected labor market conditions, particularly in the computer and engineering fields.

Finally, our sample of *government regulators* included seventeen respon-dents. The interviews with federal regulators included sessions in San Francisco with a supervisory immigra-tion examiner from the INS, a top administrator in the DOL Western Regional Office, and an INS case officer who screens permanent residence appli-cations of H-1Bs. At the state level we conducted group interviews on three separate occasions in Sacramento with eight certifying officers and six labor market information specialists from the California Employment Development Division [EDD]. These respondents were asked their perceptions of local labor market and wage conditions, the efficacy of the LCA and labor certification processes for protecting U.S. jobs and wages, and the impacts of the 1990 IMMACT legislation and DOL regulatory practices.

In sum, our research strategy was two-fold. Immigration attorneys and federal and state regulatory officials were asked largely to describe in detail the actual implementation of the nonim-migrant temporary employment pro-visions of the 1990 IMMACT legislation, particularly the H1-B visa process. Employers, workers, and trade associ-ation representatives were asked for their opinions in a wider-ranging series of questions. In addition to their views of the immigration law provisions relating to nonimmigrant workers, these included the following:

- The supply and demand of labor in their industry;
- The effects (positive and/or negative) of foreign workers in their industries with respect to

such things as job competition, quality of work, and cultural diversity;

- The standard educational and professional training (and retraining) required for affected occupations;

- Prevailing wages for particular occupations and industries;

- Prevailing job search strategies and the operation of professional networks among both foreign and U.S. workers; and

- The effects of current macroeconomic conditions and recession on the ability to find employment in the affected industries.

It is this second set of questions and respondents that forms the basis of the findings and policy recommendations presented below.

Nonimmigrant Computer Workers: Who Employs? Who Benefits? Who Pays?

How do the Silicon Valley employers, computer consulting businesses, domestic and foreign workers in the computer industry, and representatives of professional associations and unions whom we interviewed view the uses of nonimmigrant "temporary" workers in the computer industry? How do these findings address the issues of job displacement and wage depression? What policy implications follow from these qualitative findings?

Silicon Valley Employers' Perceptions

In light of the increased globalization of economic and cultural relations, it is hardly surprising that, in addition to the computer industry *per se*, employers as

different as universities, government agencies, banks, and insurance com-panies are recruiting the greatest num-bers of foreign nonimmigrant computer specialists in California. Because these workplaces differ significantly as forms of economic and social organization, they are recruiting different types of foreign workers, at varying levels of educational backgrounds and skills, for different purposes, and with different time horizons and career pathways in mind. Nevertheless, nonimmigrant foreign workers with computer programming and software design skills have been recruited by all of these employers. It is thus necessary to distinguish among three distinct types of "firms" operating with significant numbers of H-1B nonimmigrant computer workers in contemporary California: (1) computer industry firms *per se* (including software companies and hardware manu-facturers); (2) computer consulting businesses; and (3) the corporate and government clients of computer consultants and consulting businesses.

Based on thirty-nine direct and participant observations and on individual and group interviews with these categories of employer in Silicon Valley, our study found that the bulk of H-1B workers hired by the California computer industry *per se* have a master's degree in software engineering, design engi-neering, computer engineering, computer science, materials engineering, and integration engineering with specific product experience. Computer engi-neering firms hire few Ph.D.s. They also hire B.S. entry-level workers infrequently, doing so only when the local market can-not supply adequate computer engi-neering degree holders with experience in their emergent product fields. These firms reported that almost all of their bachelor-level workers are hired locally.

Employers argue that there is a "dearth" of qualified U.S. computer engineers at the master's entry level. Many em-ployers believe that U.S. workers do not pursue master's degrees and that they do not combine computer science and engineering enough to qualify for product development jobs. Conse-quently, firms explained that they hire these foreign master's-level workers "strictly out of need." Some also feel that foreigners are more attractive employees because they exhibit more "drive" than U.S. workers in searching for jobs. Our respondents

do not believe that foreign workers obtained jobs through different recruiting networks than U.S. workers, claiming that they get resumes and referrals through stan-dardized processes of running advertisements, maintaining resume banks, accessing professional networks, and recruiting at universities. Several claimed that they "did not go out looking for foreigners." Most of the foreign workers entering the market at the master's level obtain their degrees from U.S. universities and are hired as F-1 students in practical training. Our sources estimated that more than 70 percent of their H-1Bs were hired as F-1s. Aside from minimum degree requirements, respondents stated that they hired workers based primarily on special requirements relevant to proprietary product development. They argued that they cannot simply retrain employees and stay competitive because computer technology changes too rapidly. The need for "timely product development" forces them to eliminate candidates who do not already possess the specialized experience they require.

Some firms that have engaged in "downsizing" over the last several years stated that they have eliminated some of their foreign workers as jobs dropped off and are trying to redirect other foreign workers away as they focus on out-placement and retraining. Many conten-ded that firms are not enthusiastic about hiring foreign workers because it is expensive. Some of these employers believe that H-1Bs do take U.S. workers' jobs. On the other hand, many conten-ded that their firms benefit from hiring foreign workers by acquiring technical skills quickly, adding cultural diversity to the workplace, and expanding foreign markets. Moreover, they reported that well more than 60 percent of their H-1Bs eventually are sponsored for permanent residence.

Computer Consulting Firms

Our study also included in-depth interviews with representatives of five computer consulting businesses that supply foreign workers to the computer industry, the U.S. corporate sector, and agencies at all levels of government. The consulting firms included four U.S.-based subsidiaries of Indian corporations and one U.S.-owned firm run by an Indian

M.B.A. The latter employs both Indian and U.S. computer consultants in relatively equal proportions. All of these firms provide software design services in several profitable niches within the computer industry. These firms offer teams of software engineers, applications programmers, and systems analysts to *two* primary markets: (1) computer manufacturers wishing to develop systems software but without software departments; and (2) large corporations, such as banks and utility companies, developing alternative d-base systems in UNIX and graphic interface windowing environments [GUI].

India now is regarded widely as a leading source of expertise in these areas. The firms that are subsidiaries of larger Indian companies can facilitate both incountry consulting teams and offshore processing teams in India. Representatives of these firms reported a virtual "explosion" in business from major U.S. corporations that are converting data bases from large mainframes to more flexible UNIX d-base systems. According to these firm representatives, the labor pool of UNIX and GUI experts in the U.S. is absorbed and U.S. d-base designers tend to stay away from the more menial coding and testing tasks that the consulting firms execute.

Note that, between 1993 and 1995, the consulting firms whose executives we interviewed have changed their compensation and visa use practices in response to tightening of wage compliance and stricter B-1 visa enforcement. They have eliminated the use of B-1 visas for all but short-term assignments that involve the training of U.S. workers in installed systems (with compensation from Indian subsidiaries). These executives stated that 80 to 90 percent of their foreign consultants enter the U.S. with an H-1B visa for several assignments of varying duration over a term of one to three years. In response to the changing poli-tical climate and the increased availability of "temporary" U.S. computer workers with corporate downsizing of the per-manent workforce in the industry, one consulting business now hires 50 percent of its consultants locally and several others have plans to hire U.S. consultants. They expect that this will improve their workforce and profile in the industry.

All of these respondents stated that they also have eliminated in-kind payments as

components of salary and pay the full cash salaries stated on H-1B and labor certification applications. However, even these firms acknowledged that other consulting firms that supply nonim-migrant computer workers to U.S. employers still count in-kind payments as salary and defend it on the grounds that they must assist Indian workers materially because they have difficulty securing apartment leases and car loans or because they have no local credit. None of the firms stated that they fine consultants who break their contracts. They all acknowledged that some of their workers, in their words, "desert" their companies when U.S. firms offer them employment with permanent residency sponsorship.

Only recently have these consulting firms started sponsoring H-1Bs for permanent residence. Firms currently are spon-soring H-1B workers and claim that the longer-term residence facilitated by the H-1B visa, as opposed to the B-1 visa, is decreasing the flowback to India and inserting these foreign workers into the permanent U.S. workforce.

These respondents firmly believe that U.S. business practices of requiring up-front experience without offering ade-quate training and nurturing of recent graduates will keep U.S. companies dependent on temporary Indian personnel. While there is no difference in the quality of U.S. and foreign workers, they believe that U.S. companies focus too much on short-term quarterly performance instead of human develop-ment, thereby creating a pool of U.S. workers with requisite degrees—but without experience—who are viewed as functionally unqualified for time-intensive product development.

Skilled Worker Perspectives

Our ethnographic interviews with U.S. and foreign workers in California included interviews with a sample of eight foreign and eight U.S. skilled workers, mostly employed in the computer industry. Additionally, relying on the Internet, we conducted eleven other focused but open-ended interviews by e-mail and telephone. This generated data from eight additional U.S. workers and three additional nonim-migrant workers. As our Internet call for inter-view respondents was sent out nation-wide to two skilled-worker user

groups, eight of the eleven workers we attracted by this method worked in states other than California, mostly in the fields of university teaching and postdoctoral research.

The Foreign Workers' Perspective

In our California sample we interviewed directly eight foreign workers, one of whom represented an Indian professional association. Four of the Indian consultants came to work in the U.S. on H-1B visas sponsored by Indian-based consulting firms in Silicon Valley. All followed a similar pathway to gain employment as H-1Bs. They had prior experience working for the parent company in India and expect to return to the Indian operations after completion of their U.S. assignments unless they apply for permanent residence. Cur-rently, only one intends to pursue permanent residence. These respondents have bachelor's degrees in computer science and electrical engineering from Indian universities and specialize in writing software for relational databases (UNIX), products being developed extensively for major corporations within and outside the computer field.

These consultants described their work in the U.S. as providing software services that complement existing U.S. software programmers and engineers within company-specific contexts. They do not believe that they displace U.S. workers but rather offer "made-to-order skills" that enable U.S. firms to acquire necessary expertise quickly and economically by eliminating the need for recruiting, retraining, and reshuffling workers.

These foreign consultants are split on whether the supply of qualified U.S. computer workers meets the demand in the industry. Those who do not believe there is a shortage of qualified U.S. workers claim that H-1B consultants are hired because they can be acquired more quickly than U.S. workers as consulting firms keep diversified pools of consul-tants on hand. All of them believe that the demand by U.S. firms for Indian consultants will remain high as long as firms continue to treat their workforce as a short-term "dispensable" cost measured by quarterly statistics and insurance premiums. They criticized U.S. firms for neglecting the

training and development of professionals in ex-change for drawing upon a revolving and temporary workforce that itself feels no need for loyalty to firms and only seeks higher wages.

While none of the foreign nonimmigrant respondents who work for computer consulting businesses believe they are being paid below prevailing wage, they concur that they are paid "on the low side" because they do not have degrees from the U.S., usually receive entry-level pay, and do not have access to the investment and bonus benefits of other U.S. skilled computer workers.

The testimony of four other H-1B direct hires by computer industry firms illustrates a second major pathway for foreign skilled workers to enter the U.S. labor force, particularly the computer and engineering labor force. These respon-dents received bachelor's degrees in their home country, then enrolled in U.S. universities as F-1 students for graduate study in computer science and various engineering fields. After graduating, they obtained full-time jobs in Silicon Valley firms as F-1s in practical training. They later changed status to H-1B with sponsorship from the hiring firm.

One of this latter category of nonim-migrant workers firmly believes that there is a definite shortage of U.S. com-puter and engineering workers who have master's degrees and that foreigners make up for that gap in the marketplace. He added that U.S. workers are not highly represented in graduate-level programs, that close to 90 percent of pro-fessionals with advanced computer and engineering degrees are foreign, and that foreigners also are filling more faculty positions in these areas. Three of the four respondents following this employment pathway reported that they feel that the U.S. firms they worked for actually preferred to hire nonresident aliens. One believes her firm managers hire nonresidents because they pay low salaries and often require ten-hour work days with no overtime compensation.

The Views of American Workers

We interviewed a total of fifteen U.S. workers. Eight of these worked in Cali-

fornia. These included computer consultants, full-time employees in the computer industry, and postdoctoral researchers working and seeking employment in both university and industry settings. We also interviewed seven U.S. workers from outside California who are members of the Young Scientists Network computer user group. There is general agreement from the U.S. skilled-worker respondents that their labor markets are oversupplied, that jobs are scarce, that unemployment and underemployment are more common, and that wages have stagnated. Two of the computer consultants interviewed worked as full-time employees in the defense industry in southern California until the early 1990s when they were laid off and began working as contractors. Other macroeconomic factors aside, respondents believe that, in light of economic conditions, foreign workers contribute to job displacement and wage depression. This sentiment was strongly echoed in the area of postdoctoral research in universities and industry by the seven U.S. members of the Young Scientist Network whom we interviewed by Internet.

Computer consultants feel they are being displaced by a growing number of foreign consultants in the industry since the early 1990s. They believe the 1990 immigration legislation helped to encourage the expansion of foreign-based consulting firms that now underbid U.S. firms for contracts with major U.S. corporations. These workers also pointed to outsourcing of certain kinds of computer programming as an accom-panying cause of job insecurity. The U.S. computer consultants feel that cost and time savings are the major factors driving corporate contracting of H-1B consul-tants. The full-time computer worker, who has worked in the industry for eight years and who is also a project manager, reported that her firm has been replacing full-time workers with temporary contractors. One of their major contrac-ting firms is an Indian-based company that supplies them with workers upon request. Several projects operate completely offshore through the parent company in India, while others in the U.S. are entirely staffed by H-1Bs. She claimed that the availability of workers in the U.S. is not the issue, but rather time and money are, as the firm can hire new H-1Bs as early as the next day and foreign workers are paid “far below” fees and salaries paid to U.S. workers.

U.S. computer consultants also blamed the federal tax code for worsening their prospects for job security and prosperity because it prevents them from operating independently from third-party contractors and from charging higher fees. They feel this tightening of tax regu-lations by the federal government is particularly damaging in light of current immigration policy that they believe facilitates the growth of foreign-based computer consultancies operating in the market.

Given these conditions, all of the computer-related respondents concurred that their job searches take much more time and do not necessarily result in satisfactory employment situations. A worker consultant who looks for jobs in the newspaper, at job fairs, and with the help of "head hunters," described the systems as "hit and miss" because jobs are snapped up almost immediately. Like other consultants interviewed, he con-tacts up to thirty consulting firms in seeking a placement. Another respon-dent commented that he and his fellow workers often take jobs for which they are overqualified because of the prevalence of programmers. Another expressed frustration at answering adver-tisements that seem to require wide ranges of skills and experience that he described as "humanly impossible." These jobs require sophisticated languages that he feels are rarely used in programming but are the basis upon which he is rejected for an interview.

U.S. computer worker responses also stood in contrast to the commentary from U.S. firm representatives regarding the need for acquiring specialized skills through the H-1B and labor certification processes. This sentiment was particularly prevalent among workers in the computer and engineering fields who perform relatively standardized work that does not require a high degree of specialization. The consensus among computer and engineering workers is that the skills foreign workers bring are no better than those available locally. Two of the computer consultants also stated that they do not believe that Indians have a corner on the market for skills in UNIX-based relational databases, a claim articulated consistently among the Indian-based computer consultant interviews.

Workers generally also disagreed that U.S. firms need to hire foreigners with up-front skills because they cannot afford the time or money to train U.S. workers at the outset of projects (i.e., that they need to "hit the ground running"). They believe very firmly that retraining and general adaptation to specific company products is standard operating procedure in the industry. This means that no computer worker is ever completely ready to enter a job without some training in and orientation to new and customized systems. They disagreed that foreign workers do not require the same preproject training and investment. In summary, every worker interviewed holds that pure cost reduction, i.e., "profit" is the primary reason firms hire foreign workers.

Interestingly, U.S. computer consultants characterized their role in the computer industry in terms similar to those of the Indian consultants—providing complementary skills to existing product teams. Like foreign consultants, they make their skills quickly available and engage in continual retraining to maintain a wide range of skills built up through work at multiple companies. Therefore, they believe that U.S. firms hire foreign consultants because they cost less, not because they provide sub-stantively different or better services than U.S. consultants.

These U.S. respondents, particularly those who work in the computer consul-ting fields, believe that foreign consultants are being paid "well below" prevailing wage rates. Most respondents quoted hourly wage figures for foreign consultants that were as low as one-half of the standard hourly fees for the industry. Their views contrasted sharply with the information provided in interviews with the managers of foreign-owned computer consulting businesses. The foreign workers we interviewed in this field were not always aware of prevailing hourly fees for the kind of consulting work they did, but some stated that they believe they are being paid "somewhat less" than comparable U.S. software consultants and all place themselves at the "low end of the scale."

The View from Professional Associations and Unions

In addition to employers and workers, we interviewed representatives from six professional and union associations. As already noted, these respondents varied in terms of their associations' concern about and active involvement in issues of immigration and labor market conditions for their U.S. worker con-stituencies. The two associations that represent computer consultants have been lobbying the DOL and the INS vigorously over the past two years, fighting what they see as policies that bolster foreign competition and abuse of wages and working conditions in the consulting field, including widespread use of the B-1 visa and the continued practice of paying below-market hourly wages to foreigners despite the LCA provisions implemented by IMMACT 1990. They argue that foreign workers are paid "far below" prevailing wages in computer consulting. This, in turn, constitutes unfair competition and drives down hourly consulting rates for U.S. computer consulting businesses and displaced computer engineers who have become consultants by default.

These representatives faulted the U.S. Department of Labor and the California EDD for contributing to this problem for three reasons. First, they believe that the LCA process is unenforceable in the third-party consulting environment because it masks the real employer. As the LCAs cannot be posted in the actual workplace, they end up being posted in the administrative offices of consulting firms. This undermines their potential effectiveness, as U.S. workers never see them. Second, computer consultants are hesitant to make formal complaints about depressed fees because they have very little job security in the consulting environment. Third, they argue that EDD generates too low a prevailing wage figure for consultants because it averages together the salaries of full-time workers with the fees of consultants who generally lack fringe benefits and thus command higher hourly rates than full-time workers.

The other representatives of engineering trade associations and unions that we interviewed were less immediately in-

volved in the particular issues raised by U.S. consulting firms in California. Nevertheless, these respondents stressed the adverse impacts of defense down-sizing, corporate strategies of hiring temporary, debenefited workers, un-favorable tax policies for consulting businesses, and the overall national recession as adversely affecting the life chances of their members. (For factors related to the global flow of engineers see: National Research Council 1988.)

While they were unable to account precisely for the relative employment impact of these structural factors as against immigration policies toward skilled workers, they nonetheless argued that:

- There is a trend for what one respondent described as "U.S. job shops" to be underbid by "foreign job shops" because foreign workers will accept lower wages and, thus, foreign job shops can underbid competitors;

- That foreign workers are hired not because they possess special skills unavailable locally but because they are cheaper;

- That foreign workers do contribute to wage depression by entering the U.S. market at a time of unfavorable labor market conditions for U.S. engineers;

- That the current "oversupply" of engineers is causing the most talented workers to leave engineering and enter other fields like law, business, and finance.

These organizational representatives of U.S. highly-skilled workers shared the perception of the foreign workers we interviewed with respect to U.S. cor-porate practices regarding labor training and human resource development. One even said the U.S. corporations "think of workers as throwaway items." Note also that some of these respondents regarded *outsourcing* as a far greater threat to U.S. engineers and computer professionals than competition from H-1B nonim-migrant workers. They pointed out that software programming already is being outsourced "over the wire" and that design functions may soon follow the same route. Implicit in this concern is the danger that enforcement targeted at foreign "job shops" may only accelerate the trend of American cor-

porations outsourcing contracted work to the foreign consultants' offshore firms.

Comparing Nonimmigrant Recruitment Across Scientific Occupations

As suggested above, in light of the increased globalization of economic and cultural relations, it is hardly surprising that "employers" as different as com-puter and engineering firms, biotech-nology companies, and public and private universities are recruiting the greatest numbers of H-1B temporary scientific workers in California. Because these "workplaces" are historically specific institutional settings that differ significantly as forms of economic and social organization, they are recruiting different types of foreign "temporary" workers at varying levels of educational backgrounds and skills, for different purposes, and with different time horizons and career pathways in mind. While space does not allow a detailed discussion of each of the other scientific occupations included in our larger study, it is, nonetheless, important to offer a brief discussion of our key findings regarding nonimmigrant recruitment in a selection of the other fields we studied to illustrate the specificity of our findings regarding the computer industry, to capture the complexity of developing global labor markets, and to add depth to our overall analysis.

The Biotechnology Industry

In our larger study we interviewed five representatives of three high-end H1-B user biotechnology companies in San Francisco and Los Angeles. Each of these firms hire "temporary" foreign workers almost exclusively in research and development. They actively recruit high-level Ph.D.s from the global marketplace as research project managers and post-doctoral researchers with specialized expertise in ongoing firm projects. Beyond this, they recruit all other scientists and assistant scientists locally, except when particular support people are requested from foreign labs by their H1-B project directors.

The transnational talent pool of scientists in biotechnology is small and close-knit.

Recruitment relies heavily on inter-national professional networks. The recruitment process for project managers is very thorough, with firms spending as many as six months to find an exact match of expertise. The population of foreign professionals in California biotechnology firms tends to be very diverse with no nationality constituting even close to a majority. This finding underlines the professional nature of recruitment networks and the limited impact of ethnic recruitment networks in this scientific field. These firms afford two possible pathways from H-1B status to permanent residency. Some of the sci-entists recruited are offered sponsorship upon their initial employment as a re-cruitment incentive. Others are afforded the possibility of this option after a trial period ranging from six months to two years.

Perhaps not surprisingly, in light of the above recruitment process, the biotechnology firms whose representatives we interviewed are not experiencing any problems with the H-1B process. As they recruit top scientists and pay high salaries, they do not experience any "prevailing wage" problems with state regulators. Although they did complain that the labor certification process has been slowing down and becoming increasingly "aggressive," these firms have been successful in using the "outstanding" immigration category to recruit the vast majority of their foreign scientists. They argued, and offered evidence to support their claim, that far from causing any labor displacement of U.S. Ph.D. scientists, the research and product development projects they create actually expand job opportunities for domestic biotechnology specialists because of the firms' practice of rounding out research project teams directed by foreign scientists through local recruitment.

Although our findings are limited because of the small size of our firm sample, the biotechnology firms we did select were the highest users of H-1B scientists in the state. Moreover, the recruitment processes described for each firm were remarkably consistent with each other. The findings suggest that neither wage depression nor job dis-placement is a serious problem in this scientific occupation. If this is the case, there is little need to consider any sweeping policy change for this sector. Put colloquially: "If it ain't broke, don't fix it."

University Teaching and Research

Our employer sample of university administrators of immigration programs included eight individuals representing the state's four largest university users of H-1B visas for their faculty and research staff: two large public uni-versities; one large private university; and one moderate-sized elite private university. We also addressed the employment conditions of Ph.D. sci-entists in university teaching and research with a sample of nine U.S. respondents and three foreign respon-dents with doctoral degrees, drawn from both our ethnographic and Internet samples of scientific "workers." To sup-plement these qualitative interviews, we attended a half-day meeting of the Bay Area Foreign Scholar Advisors, repre-senting the four universities in our sample and twelve other public and private universities throughout Cali-fornia. Finally we conducted participant-observation research at a half-day workshop held at one of our major public universities for foreign Ph.D.s moving into U.S. labor markets.

The universities we sampled hire foreign workers mostly as faculty and postdoctoral researchers. The averages derived from data provided to us by the four largest university users of the H-1B visa category were 30 percent faculty and 70 percent postdoctoral researchers. All of the faculty are selected by a scrupulous process for the recruitment of tenure-track employees and nearly all are sponsored for permanent residence as a condition of employment. The use of H-1B visas for this category of employees functions largely as a "holding pattern" while permanent residency approval is sought. In contrast, postdoctoral researchers generally are sponsored for H-1B visas with departmental approval and verification of the availability of three years of research funding. The two principal pathways by which foreign doctoral-level scientific workers receive H-1B visas are conversion from F-1 and J-1 visas. University representatives reported that the positions filled by the J-1s and F-1s are advertised for general recruitment before foreign candidates are approved for H-1Bs to allow access of others in the market to the positions. While foreign-born faculty and post-doctoral researchers are spread through-out departments, university employers reported that there is some clustering in engineering, computer sciences,

business, and medicine and among Indians and other Asians.

University immigration administrators expressed great concern over the issue of prevailing wage determinations. While the EDD, the California State Employment Security Agency [SESA], employs a national survey, *Academe,* our four sampled California campuses argued that the survey generates exces-sive salary quotes for junior faculty because it amalgamates faculty salaries for all levels without recognizing traditional tenure step systems. Em-ployer respondents were adamant that the EDD fails to understand how universities function and disregards their own wage scales that reflect statewide salary conditions and the multiple layers of university rank and step systems. Further, they pointed out that conducting *ad hoc* local wage surveys is not a feasible way for them to offer alternatives to the amalgamated *Academe* surveys because often the university is the only institution of its kind in its local labor market.

The university administrators with whom we spoke advanced the argument that they should not be subject to H-1B regulatory constraints at all because universities, as institutions, always have sought, and indeed require, foreign scientific professionals for intellectual exchange and to fulfill their research and academic missions. As nonprofit organi-zations in the service of the advancement of knowledge, they further argued, they should not be expected to compete with corporate professional salaries in private industry. They advocated instead the creation of a special H-1C visa category for universities that does not have a nu-merical cap, stringent wage verification procedures, or severe penalties.

The employment conditions of the Ph.D. scientists whom we interviewed in our university sample of scientific occupa-tions varied greatly, ranging from full-time, tenure-track faculty members and research scientists to postdoctoral researchers working in their fields, to those working in temporary positions outside the field of their Ph.D.s. Despite notable differences in personal work history, these respondents converged in describing four contemporary trends in their respective scientific fields: (1) an oversupply of Ph.D. scientists in their labor market; (2) reduced

opportunities for permanent positions in university teaching and research; (3) a resulting substantial prolongation of time spent as low-paid postdoctoral researchers prior to entry into their field, where they are treated as temporary workers with reduced or nonexistent benefits; and (4) a growing abandonment of some highly oversupplied fields by Ph.D. scientists for better paying work in other fields that do not require the graduate education they spent so much time and money to acquire.

While the U.S. respondents with Ph.D.s acknowledged the positive impact of foreign scholarship on university life, they also worried about competition from foreign Ph.D.s for increasingly elusive faculty positions. Some of our respon-dents reported that U.S. scientists with doctoral degrees shy away from university-based research positions because of low wages, thereby selecting themselves out of the market. Some of the U.S. Ph.D.s we interviewed, who have entered other fields in private industry, said they were forced out of this market by a combination of low wages, extreme overproduction of both U.S. and foreign Ph.D. scientists by American universities, particularly in physics and mathematics, and exploitative working conditions in postdoctoral research labs. They argued that foreign Ph.D.s are willing to accept such conditions because they see low-paid postdoctoral research as a key pathway to a green card. A few of our U.S. respondents have accepted work in fields completely unrelated to their fields simply to earn a living wage. Two high energy physicists, for example, have gone into computer programming and managing a biology laboratory because they cannot find any work in their own fields. Several others in our sample were encountering extreme difficulty securing any but the most temporary, insecure, and nonbenefited university postdoctoral research positions.

Further exacerbating this problem is the practice by universities in California and elsewhere of downsizing their operations and increasing their use of temporary employees, both domestic and foreign. As there are no established Dictionary of Occupational Titles [DOT] codes for postdoctoral workers, universities can offer very low salaries to postdoctoral

researchers, often financed by soft money. They also can offer limited fringe benefits and remain unchallenged as U.S. sci-entific workers continue to exit this mar-ket, discarding their long human capital investment in Ph.D. study, while foreign postdoctoral researchers remain quiescent, and, sometimes, even accept exploitative working conditions. We were told, for example, of Chinese post-doctoral medical researchers in a major California university who were hired as quarter-time researchers under prevailing wages but who spent more than fifty hours per week in their labs in hope of obtaining sponsorship and remaining permanently in the U.S. with green cards.

University representatives have made a coherent case in support of the general proposition that universities are permanently in need of a steady infusion of foreign talent to engage in their basic tasks: cutting-edge research; the general advancement of scientific knowledge; and the production of new knowledge that has general public benefit. They argued that they should be exempt from the stringent regulations that apply to profit-making businesses regarding H-1Bs and labor certifications. Based on the findings of our study, the case for their argument is considerably stronger in the case of their recruitment of full-time, tenure-track faculty members than in the case of part-time faculty and temporary postdoctoral researchers.

In the former case, the universities engage in extensive formal search requirements, multiple interviews, and, at the time of our study, the need to conform to strict affirmative action guidelines. In this search they clearly are advantaged in obtaining the best available talent world-wide by the great oversupply of Ph.D.s that they have generated, particularly in some scientific fields like mathematics and physics. While their graduate degree programs may be faulted for insensitivity to existing labor market conditions, when they recruit new tenure-track faculty, the quality of candidates' research and, to a lesser extent, their teaching skills are paramount. Thus, the recruitment by universities of permanent teaching and research faculty tends to be driven by an open search for the best talent world-wide, rather than by a desire to reduce costs.

In contrast, in the case of university postdoctoral researchers, wide discretion is left in the hands of principal investigators, often operating on soft money from external grants. These "employers" depend on a steady infusion of relatively low-paid postdoctoral researchers to keep their research going. Hiring often is done by means of personal social networks, both professionally and ethnically based. The quest for excellence often is superseded by the mutual cultivation of mentor-mentee relations between principal investigators and postdoctoral candidates. The search for candidates is limited as well by the differential willing-ness and ability of U.S. and foreign Ph.D. researchers to work long, often uncom-pensated, overtime hours for relatively low salaries.

In view of the above findings, our larger study makes three policy recommendations:

- That immigration policy makers limit any proposed establishment of a less restrictive scientific worker immigration category for universities, such as a proposed H-1C visa, to full-time, tenure-track, teaching and research occupations;

- That, in enforcing existing regulations, state and federal regulators of prevailing wages pay attention to the reasonable arguments university representatives have made concerning the uniquely layered and segmented tenure-step systems that constrain the salaries that can be assigned within the full-time, tenure-track teaching and research system; but that

- Because of the potential for general wage depression, abusive working conditions for foreign postdoctoral scientists, and job displacement of U.S. scientific researchers in the postdoctoral occupational cate-gory, the regulatory process should concentrate scarce enforcement resources upon and insure prevailing wages for the postdoctoral researcher occupational category. Creating such a less-restrictive visa category for faculty employment would complement this recommendation by freeing up resources to be deployed in the job category where they are most needed.

The New High-Tech *Braceros* Revisited

Having focused this research paper largely on the processes of nonimmigrant recruitment and employment in the computer sector, what are the policy implications and recommendations that follow from our findings? First and foremost, computer software work is complexly articulated in distinct occu-pational niches in the U.S. and world economy and should be understood and dealt with as such. When designing policy change it is thus crucial that the "real employer" of nonimmigrant skilled computer workers be recognized and addressed in the future.

We have seen that one of the key changes in the computer industry springs from its corporate restructuring by expanding the number of temporary workers while reducing its full-time workforce. In the industry itself there is a labor surplus, not a shortage, as software engineers leave full-time employment in computer companies, particularly defense-related firms. At the same time, occupational data show that the positions of software engineer, programmer, and coder are growing at a rapid rate both in California and nationally. How do we explain this anomaly?

The answer is twofold. First, computer firms in Silicon Valley are shifting from hardware to software applications, downsizing their permanent workforce in Silicon Valley and worldwide, and relying increasingly on contract labor to perform software design, programming, and coding functions. Second, corpora-tions of all kinds outside the computer industry are picking up many of those displaced from the industry as well as hiring H-1B and U.S. computer consul-tants as temporary workers to help them to downsize and create a more flexible workforce. Both primary data drawn from our interviews with U.S. and foreign workers and employers and abundant secondary documentary sources (e.g., ICIM International 1992:1-4; APL Management Consultants 1992:1-4) reveal that the downsizing firms relying on computer consultants run the gamut of the U.S. economy, including finance and banking, real estate, accounting, manufacturing, public utilities, pharmaceuticals, health care, the travel industry, and even government agencies at all levels.

Thus, the key question is: "Who is the employer?" The real employers of the computer workers in these occupations are neither the U.S. consulting companies nor the foreign-owned "job shops" that supply workers, but rather the clients who subcontract their services. It is the downsizing corporate and government clients who are generating the demand for temporary software consultants to assist them in restructuring. The "job shops" and consulting businesses are merely middlemen responding to the demand generated, especially from large corporate firms. The DOL tendency to regard the "job shop" as the "employer" plays into the hands of the real employers, as subcontracting is a device used to avoid legal responsibility for wage compliance and visa petitioning. Ironically, downsizing—both within and outside the industry—has reduced employment of full-time computer software engineers, programmers, and coders, thereby expanding the supply of potential consultants even further. The combined effect of this dynamic has been to depress hourly fees in this field—in some cases even lower than seven years ago.

A second irony is that state and federal regulatory agencies have spent a great deal of time trying to separate out "job shops" from "legitimate consulting businesses" (see, for example: Zachary 1995:A2). We have found that consulting agencies and "job shops" do differ from each other in the rates they pay their consultants, which, based on qualitative data from interviews, can be quite significantly lower for foreign H-1B consultants. However, we do not find the distinction to be centrally important except to the extent that wages are affected. Foreign competition does lower the prevailing wage of software engi-neers, programmers, and coders, particu-larly at the lowest levels. However, the more salient issue is that *both* types of consulting businesses merely are supply-ing the overarching corporate (and, to a lesser extent, government) demand for more efficient ways to organize work, reduce their obligation to provide fringe benefits to full-time workers, and create a more flexible global workforce.

Defense-related firms clearly have failed to retrain their existing workforce in the face of the need for conversion to civilian

production. Evidence from the professional association representatives and even the foreign workers we inter-viewed indicates that nondefense-related industries tend to be equally inattentive to such long-range considerations as worker retraining and human resource development. In the epoch of global re-structuring earlier corporate strategies of building allegiance from permanent workers by human development policies have been replaced by a race to become more flexible in the global marketplace by relying on an expendable workforce of temporary workers and shrinking an increasingly insecure permanent skilled workforce. Among computer software engineers and programmers, permanent job displacement has expanded the pool of computer consultants, increased the search time for contracts, and reduced the time available to keep skills up-to-date in a rapidly changing field.

Policy Recommendations

In light of these developments, the following policy recommendations address the real problem at hand:

- Regulatory and enforcement mechanisms should focus on the "real employer," i.e., the clients of contract workers, including holding them accountable for paying prevailing wages to nonimmigrant workers and for retraining displaced American workers;

- To this same end, the Education and Training Administration [ETA] in the U.S. Department of Labor well might focus its efforts on creating retraining opportunities for displaced U.S. workers;

- Displaced skilled workers also should be offered tax credits or deductions to cover the costs and time of retraining.

As a corollary to these interrelated policy recommendations, as H1-B consultants do appear to contribute to wage depres-sion, it is finally recommended:

- That the DOL focus its efforts on monitoring this aspect of the so-called computer "job shops" to insure that they pay their work-

ers prevailing wages, rather than targeting them as the sole culprit responsible for U.S. worker displacement.

Conclusions

By and large, high-skill workers in the computer field have been displaced by corporate downsizing, both inside and outside the computer industry, not by competition from foreign H-1B workers. There is no doubt that expanding the size of the labor pool by the entry of H-1B software engineers, programmers, and coders increases the difficulty U.S. computer consultants are experiencing in finding a steady supply of work. Yet, they are finding work, as the demand for temporary computer software con-sultants remains high. The main prob-lems U.S. computer consultants face are stagnant consulting fees and a highly-competitive environment for consulting work that contributes to continuing income stagnation. The complaints U.S. workers voice about foreign competition stem from the fact that, in the current political climate, this is an issue they can do something about by acting to "stop immigration." But the structural displacement produced by downsizing is a much larger problem—in the computer field and elsewhere—that can be addressed by serious efforts to enforce prevailing wage standards and develop proactive policies to retrain an increas-ingly insecure segment of the U.S. workforce.

In the final analysis, because of the growing reliance of U.S. industry, commerce, and government on outside consultants, it is important to map the complexity of the emerging consulting sector of the U.S. and global labor market. In today's age of flexible production, all categories of employer are turning increasingly to consultants to perform project-specific operations. This study focused intensively on computer consulting as a business and software engineers as workers. But the policies and practices identified in the foregoing analysis may be applicable more generally to address the rising tide of temporary consulting workers nationally and worldwide.

Despite this likely convergence, it is important to raise a cautionary note by recalling our comparative analysis of the recruitment and employment of nonimmigrant scientific workers in other fields.

Clearly, global recruitment and employment processes in biotechnology research and development, university teaching and research, and computer software engineering operate in fundamentally different ways. Thus, to design reason-able policy responses to contemporary conditions, policy changes concerning nonimmigrant employment regulations need to be considered carefully, on a case-by-case basis, both across scientific fields and between different job categories within particular sets of workplaces. To do otherwise is to fly in the face of the complexity of the global world we have created and the transnational networks that now sustain it.

That very complexity poses the paradox now facing national regulatory environments in today's global economy. By allowing a steady flow of highly-skilled specialty workers to enter the United States for relatively long temporary periods at prevailing wage standards, contemporary immigration law has made regulatory officials responsible for administering a *de facto* guest worker program. If regulators set prevailing wage standards too low, they become subject to the political charge that they are running a "high-tech *bracero* program" that hurts American workers. On the other hand, if they set them unreasonably high or make domestic access to nonimmigrant workers too bothersome for U.S. employers, they run the risk that U.S. firms presently employing nonimmigrant workers simply may switch from a policy of importing skilled temporary workers to one of exporting the work that they do to knowledge production sites in less-developed countries like India and Pakistan or in Eastern Europe where needed skills and technological means of communication already are concentrated. In the field of computer consulting such outsourcing already is happening. If the pace and scale of outsourcing is accele-rated by cumbersome or exclusionary immigration policy, both regulators and policymakers will be held politically responsible for creating a "high-tech *Maquiladora* program." In our contem-porary political climate, the paradoxes of economic globalization indeed are coming home to roost.

SKILL LEVEL AND EMPLOYER USE OF FOREIGN SPECIALTY WORKERS

JACQUELINE HAGAN AND SUSANA McCOLLOM
UNIVERSITY OF HOUSTON

Employers increasingly rely on a well-educated and highly-skilled workforce to meet the competitive demands of today's global economy. The Immigration Act of 1990 responded to a perceived shortage of skilled workers by increasing the number of both economic-based immigrant and nonimmigrant visa categories. Most significant and controversial among these changes was the reclassification of the H visa category, which remains since it's inception in the Immigration Act of 1952, the largest program supplying temporary foreign workers to U.S. employers.

Originally, the H program was conceived as a mechanism for tapping into a labor pool of temporary foreign workers to meet bottlenecks in the supply of U.S. workers in particular occupations.[1] The 1990 Act streamlined the procedure by which employers gain access to skilled foreign labor by replacing the "distinguished merit and ability" requirement with a simplified "specialty occupation" clause and increased dramatically the number of foreign workers that U.S. employers could bring into their workplaces for periods of as long as six years.[2]

[1] In addition to the H-1B subdivision (the H-1A being discontinued), the H program includes three other types of temporary foreign worker categories: the H-2A subcategory is reserved for temporary agricultural workers, the H-2B for temporary nonagricultural services not exceeding a year, and the H3 for a relatively small number of certain trainees.

[2] A specialty occupation under the 1990 Act is one that requires the practical and theoretical application of specialized knowledge and attainment of at least a bachelor's degree in the specified specialty.

However, following passage of the 1990 Act, the United States, along with a number of other industrialized nations, was swept into a global recession that translated into severe cutbacks in research funding, corporate downsizing, and high unemployment. The hardships of the latest economic cycle reinforced an ongoing trend of significant realignment and reorganization of the production of work. Moreover, such shocks were felt especially hard in the fields of science and technology: many skilled workers in these areas lost their jobs and well-trained recent college graduates confronted shrinking employment opportunities. Despite this, the number of H-1Bs filed has risen steadily each year since 1990 and they are concentrated in the fields of science and technology. These interrelated developments raised a number of questions regarding the effects of the H-1B program.

In response to these developments, in late 1993, the U.S. Department of Labor [DOL] sponsored several in-depth field studies to examine how the H-1B system works and how it affects the various actors, including domestic and foreign workers, professional associations, government officials, and immigration attorneys. In selecting the research sites, DOL sought states with a high number of H-1B applications in the areas of science and research but with different labor market conditions. The research reported on below was conducted in Texas in 1994, a time of economic expansion following a prolonged recession in the state.

The Economic Context of Foreign "Specialty" Workers in Texas

In the 1980s, almost a decade before the rest of the nation, the Texas economy experienced what became a world-wide recession. Beginning in 1982, an oversupply of oil in the world market sent the prosperous Texas economy into a severe five-year recession. Unemployment increased steadily during this period, peaking at roughly 9 percent by 1986 (Smith 1989). Given Texas' historical dependence on oil and petro-chemical production, no metropolitan area, industry, or occupational group was spared the recession's repercussions. As the center of the world

petrochemical industry, Houston was especially hard hit: the area's unemployment rate stood as high as 13 percent in 1986; declines in manufacturing, business services, and construction resulted in a loss of more than 200,000 jobs in the city between 1982 and 1986 (Hagan & Rodriguez 1992).

In response to the recession, large petrochemical and engineering firms headquartered in Houston initiated a restructuring strategy—a process that continues to the present. Typically, these multinational corporations [MNCs] retained those components of the business that they did best. In most cases, this involved keeping and retraining very highly-skilled employees in software design and engineering and outsourcing lower-level tasks, such as programming and coding. The elimination of salaried positions enabled these companies both to maintain production levels and remain competitive.

In some cases, downsizing—or "right-sizing" as it is euphemistically referred to by the corporate executives interviewed—involved laying off more than 40 percent of a firm's workforce. This strategy had particularly severe consequences for engineers, computer programmers, and analysts who comprised the information systems and research and development components of multinational corporations headquartered in Houston. Software analysts and programmers, who had earned high annual salaries (as much as $80,000) during the boom years, entered the ranks of the unemployed. Computer consultants, who had carved their own niche in the booming information and support components of the petrochemical industry, no longer were able to secure long-term projects at the high hourly wages (as much as $65) that they once had enjoyed.

A shift from a goods-producing to a service-producing economy, beginning in the late 1980s, started Texas on the road toward economic recovery. By 1990, the Texas labor market ranked third nationally in employment. The unemployment rate dropped to 6 percent by the close of 1990, a level it still maintains (Texas Comptroller of Public Accounts 1996). In 1995, Texas led all states in the number of new jobs added annually; currently Texas ranks tenth in the nation in the rate of

employment growth. The state's early emergence from the recession was due, in part, to the development of a more diversified economic base and the continuing relocation of high-tech industries to Texas. While oil and gas production are still an important sector of the state's economy, Texas is now less closely tied than it was to these volatile industries. For example, it is projected that, from 1993 to 2000, employment in the mining industry, especially in the areas of crude petroleum and natural gas extraction and oil and gas services, will decline by as much as 40 percent in some areas of the state. On the other hand, employment in service-producing sectors is large and growing: 96 percent of employment growth in Texas by the year 2000 is expected to occur in service industries (Texas Employment Commission 1992, 1995).

Expansions in business, engineering, and health services drive overall growth in service-sector jobs. While total wage and salaried employment for the state is projected to grow by 16 percent between 1993 and 2000, employment in business, engineering, and health services is projected to increase by 41 percent, 40 percent and 31 percent, respectively. Many of the growth occupations in these sectors are those in the higher-skill and knowledge-base areas. For example, computer-related jobs currently rank first among the fastest-growing skilled occupations. Computer system analyst and computer engineering positions are projected to increase by more than 58 percent from 1993 to 2000. The number of computer programmers also is expected to increase by 40 percent during that period. Other high-growth skilled occupations include science-related jobs in teaching and research, which are expected to grow by more than 30 percent before the year 2000 (Texas Employment Commission 1995).

It was within this context of economic expansion and healthy employment prospects for well-trained U.S. workers in science and research that a team of researchers studied the role of H-1B foreign specialty workers in the Houston and Austin area labor markets. That research forms the basis for the findings and recommendations discussed below. The chapter first discusses the project's methods, its manner of selecting firms in the research, academic, and computer indus-

tries, and its mode of inquiry. The chapter then separately presents the findings on, and recommendations for, the H-1B program in research universities and medical centers and in the complex computer industry. The conclusion identifies lessons from the study of the H-1B certification process that can be used to improve the program.

Methodology

The research reported on below is based on a 1994 field study supported by the U.S. Department of Labor's Bureau of International Labor Affairs and conducted by a team of researchers in Texas. Texas was selected as one of several research sites for the larger study because of its high national ranking in the number of H-1Bs filed and because it is the location of a DOL/ETA [Employment Training Agency] regional office. This agency is responsible for approving the Labor Condition Applications [LCAs] of H-1B petitioners and supplied the Texas team with list of ranking H-1B user firms in the state.

The primary goal of the DOL study was to understand better how the H-1B system works and how it affects those involved. To identify the interplay of the various actors in the H-1B process, the study centered on the firm as the unit of analysis and relied on a qualitative field methodology that was best suited to capture process and variation over time. Open-ended interviews were conducted with all actors involved in the recruitment, employment, and regulation of H-1B workers. The total sample included regional DOL and Texas Employment Commission officials, managers, U.S. and foreign workers in heavy- and light-user H-1B firms, private immigration attorneys, firm representatives responsible for preparing H-1B applications, and representatives of professional associations.

The original firm sample size of thirty included a variety of public and private educational institutions and a range of computer engineering firms. The firms were selected according to their size, public-versus-private status, and variable usage of the H-1B specialty skilled workers in science research and teaching, engineering, and computer-related occupations. Most of the large corporations and engineering firms and a number of the firms involved in computer applications and

servicing are located in Houston; a smaller number of firms concentrating in software development are located in Austin. Public and private universities included in the sample are distributed in various cities across the state.

Once in the field, however, we were refused interviews by a number of the employers. Still others blocked access to their employees and their attorneys. By the end of the eleven-month field study, we had conducted thirty-one interviews with individuals representing twenty-three firms. In addition, we visited research laboratories of medical centers and universities in which H-1Bs are temporarily employed as postdoctoral fellows and associate scientists and conducted telephone interviews with several of the principal investigators of these research endeavors.

We had the most success in gaining access to workers. Within the twenty-three sample firms, we interviewed approximately seventeen H-1B foreign specialty workers and thirteen U.S. skilled workers. Most were interviewed a second time by telephone to monitor employment and immigration developments. The occupations of both the foreign and U.S. workers in the sample range from high-level computer analyst and life scientist to computer programmer and university postdoctoral fellow. We attempted to ensure that both foreign and U.S. workers were represented in high-skill and lower-skill professional occupations within the firms.

The U.S. worker interviews were supplemented with three interviews with leading representatives of professional associations for university professors, mechanical engineers, and computer consultants. One respondent is a past president of a national association of computer consultants and active in lobbying efforts for greater enforcement of prevailing wage provisions in the H-1B and permanent certification programs. Additionally, we attended the political action committee meetings of U.S. computer programmers and analysts vigorously lobbying for the elimination of the H-1B program. The U.S. worker perspective was explored further by reviewing dozens of official complaints to DOL from U.S. workers.

Our sample of attorneys includes eight private immigration attorneys, seven of whom represent the sample firms in their

petitions for H-1Bs. The study sample also includes a number of government officials charged with processing and regulating H-1B applications. We conducted telephone interviews with regional and national INS representatives charged with screening and processing permanent certification, including those of H-1Bs. We visited the DOL/ETA regional office and interviewed the regional DOL certifying officer, the H-1B officer, and the office computer programmer. The regional office was instrumental in explaining the steps of the certification process. It also provided the research team with updated lists of employer names to use for the selection of firms. The research team also conducted intereviews with staff of the Texas Employment Commission [TEC], the state agency responsible for providing prevailing wage data for specialty occupations.

The questions asked during the interviews varied by respondent category. Government officials were asked to describe the H-1B process from the perspective of their official task and to identify weaknesses or bottlenecks in the system with an eye towards improving interagency communication. Wage and hour officials were asked to describe in detail problems particular to the prevailing wage issue in various occupations and industries and variations across public and private firms. Employers, employees and professional association members were asked a series of open-ended questions concerning: (1) the dynamics of the supply and demand of workers and their industry; (2) economic transformations in their industry; (3) company-level restructuring strategies; (4) recruitment methods; (5) prevailing wage issues; (6) workforce composition; (7) changing skill demands; and (8) perceived effects of the H-1B program on their industries. Employees were further asked to track in detail their education and work history. H-1B workers were asked to provide a detailed immigration history, including information on transitions to and from other immigration statuses.

The Texas research team was most successful in gaining access to all involved parties in computer industry firms and in medical and university research settings. The following two sections outline our key findings regarding the usage of H-1Bs in these labor market sectors.

Internationalization of Scientific Research: Demand for Highly-Skilled Foreign Workers

Within the science and medical areas, our firm list included four very large medical centers and three research universities. Foreign researchers on H-1B visas were found overwhelmingly in the following departments and laboratories: Biochemistry, Molecular and Human Genetics, Cell Biology, and Engineering. They were recruited as research associates and research fellows by departmental heads and principal investigators to work on funded research projects, most of which are federally supported by the National Institutes of Health [NIH] and National Science Foundation [NSF]. All are involved in high-level research and development positions on the basis of their highly specialized expertise.

The projects on which H-1Bs work alongside U.S. scientists in these laboratory settings are often at the cutting edge of science and involve research of a defined and complex area (e.g., megabase DNA sequencing of certain chromosomes). Research personnel must be not only highly skilled, but well-trained and well-versed in their area of expertise to meet the deadlines of funded research.

Project directors and department heads argue that there are not enough qualified U.S. candidates that meet these criteria. The following comments by a chair of a Biochemistry Department and by a Professor of Cell Biology explain the difficulty in recruiting qualified candidates:

> Having a Ph.D. alone is insufficient to qualify individuals for careers in science. The background and training, as well as the research interests, become very important factors in hiring such individuals because a principal investigator must produce meaningful results within a prescribed period of time. To train and retrain takes more time than is available to most principal investigators. These cutting-edge research projects do not involve routine experiments, but require continuous probing of the unknown. . . . Such probing requires highly sophisticated experimental tech-

niques that only a few individuals are trained to perform. Therefore only a few qualified scientists are available to hire.

We have tremendous difficulty hiring qualified personnel for postdoctoral fellow positions in my laboratory. We've done local, national, and word-of-mouth searches. Many of the candidates have not been qualified. We require a candidate to have previous training and experience in cell culture and molecular biology. This training is essential to meet NIH deadlines. We simply cannot afford to spend three to four months training personnel when you consider that three-year NIH RO1 grants are due for renewal at the end of twenty-four months; well, it takes two to three months to find and hire someone, another few months to train them.

In all of these departments and laboratory research settings, both foreign and U.S. workers and their employers agree on the importance of H-1B visas in advancing research. Both U.S. coworkers and employers of foreign workers state that without access to the specialized skills of foreign labor, the quality of scientific research in the United States would severely decline. They believe it to be a vital component in the functioning and success of the research process, as the following quotes illustrate:

There is not a large enough supply of U.S.-born students in the hard sciences. The best person should be taken for a post-doctoral position. I would rather be surrounded by the best there is than simply by Americans. It doesn't work in this field to give U.S. workers all of the jobs (a U.S. postdoctoral student in cell biology).

Our research in Cell Biology and Neurology is fundamental to our understanding of learning processes and the diseases that affect them, that is diseases such as Alzheimer's and Parkinson's. We are considered by others in our field as one of the leading laboratories among the international community. If my four H-1B as-

> sociates had not been able to obtain the visa, it would have had an enormous impact on my research program. Suffice it to say that the quality and quantity would have been substantially diminished, my ability to secure federal and nonfederal funding for the research would have been sharply curtailed, and I believe that my laboratory would not be recognized, as it is, as one of the leaders in our field. H-1Bs are essential if U.S. laboratories are to remain competitive among increasingly sophisticated laboratories in the rest of the world (Professor of cell biology and neurology).

Foreign workers appear essential to the functioning of scientific research in universities and medical centers. Without them, we were repeatedly told, research institutions would lose their competitive global edge in technological and scientific research. All representatives of these institutions, including departmental heads, laboratory advisors, and coworkers agree on the important contributions foreign workers bring to their research environments. Not only does it allow the United States to maintain its competitive edge in the global science and technology community, but it may also provide jobs for U.S. counterparts for collaborative research and technical support positions.

Shortage of U.S. Researchers

Employers in scientific research repeatedly commented on the shortage of U.S. graduate students to fill research positions in the hard sciences. There is a declining number of U.S. students entering U.S. graduate programs in science, countered by a simultaneous increase in foreign students—whose nations' educational institutions and economies have grown tremendously over the past few decades—coming to U.S. universities to study science, math, and engineering. Similarly, many new Ph.Ds, especially U.S.-born graduates, increasingly are lured to the higher salaries and less demanding work schedules afforded by private industry. Foreign-born graduates of U.S. universities, most of whom are on a J-1 student visa, are at a disadvantage when it comes to locating permanent employment in

private industry, which appears to favor U.S.-born candidates. The culture of scientific research is far more diverse and flexible; research teams in laboratory environments are typically composed of diverse groups of foreign and national scientists.

Scientists employed in research universities and medical centers, especially postdoctoral fellows, do not seem to be motivated by the often rather meager earnings offered by these institutions. Nevertheless, if the monetary rewards were greater, we might have more U.S. workers seeking careers in hard science. If, somehow, the supply of foreign workers dried up, it might well place upward pressure on wages for principal researchers and, especially, support staff. However, it does not follow that the federal funding that is a major source of U.S. basic research monies would increase to meet that need. Would the forprofit marketplace then be pressured to invest more money in basic research within the U.S. or would it move operations offshore? Further, it is unclear whether the declining number of U.S. researchers in the sciences is merely a problem of financial incentive. The declining number of U.S. scientists is, some argue, more fundamentally a result of changing secondary school curriculum, attitudes towards the rigor of scientific work, and a lack of federal support for science education.

Departmental heads and educators acknowledge that foreign students attend and support our universities because of the premier research and learning opportunities available. They subsequently compete to work in university and medical center environments because of their advanced technological environments and opportunities to work on cutting-edge research projects with some of the best scientists in the world. Employers fear that it is only a matter of time before graduate programs and research laboratories in their home countries reach sufficiently sophisticated levels to keep foreign researchers home or to draw those in the United States back home. Department chairs and laboratory advisors express their good fortune in having foreign researchers as part of their research teams and fear the day when foreign researchers and scientists will no longer seek research opportunities in the United States. These same fears were expressed by several U.S. postdoctoral fellows working in

a biochemistry lab at a prestigious medical center. As one recent graduate explained:

> There is a new trend among graduates in Chemistry. While many of the U.S. graduates increasingly favor private industry employment, more and more foreign-born graduates are returning home once they complete their education and training.

Professors in several of the study universities told us that this pattern is increasingly adopted by Korean- and Taiwanese-born doctoral graduates of U.S. science and engineering programs. Indeed, the return migration of foreign scientists to their homelands made national news in 1994 when distinguished chemist Yoan Lee, a long-time U.S. resident and Nobel Prize winner, made the U-turn and headed back home to direct Taiwan's prestigious Academia Suniea, an impressive conglomerate of twenty-one research institutes.

In sum, the H-1B visa does not appear to be abused by employers in universities and large medical centers. Positions are filled on a competitive basis and recruitment occurs at both a national and, increasingly, global level. Moreover, competition varies by the reputation of the project director and prestige of the grant. Often, interested candidates approach scientists under whom they wish to work. In this context, professors lacking an established research record have the most difficulty locating qualified candidates. Salaries are low compared to those in the private sector, especially for postdoctoral fellows, whose salaries are largely determined by federal funding sources and can run as low as $21,000 per year. Despite these meager earnings and uncertainty of employment once the H-1B runs out, many foreign postdoctoral fellows continue, at least for now, to be drawn to the technology and research opportunities available in U.S. research institutes, especially the opportunity to work with distinguished scientists on prestigious grants. As we might expect, some H-1Bs are drawn to the U.S. because of the lack of research opportunities back home. For these workers, the elusive green card eventually becomes a common goal. As one H-1B postdoctoral fellow working in a robotics research laboratory told us:

> In Tunisia [his home country], there is a glut of scientists with Ph.Ds from American Universities, but no research opportunities for them back home. Many of us came on J-1 student visas. Our education was paid for by our government or yours. But how could they expect us to return home to nothing once we had been exposed to the most advanced research in the world?

More common, however, are statements by many who predict a future in which more Yoan Lees will return home to work in high-tech companies and research institutes created by their governments. The ability of U.S. research institutes to continue to recruit workers from an international labor pool of highly-qualified persons remains an open question. This issue, while rarely raised in immigration policy debates, permeated our interviews with research personnel. As the U.S. government hints at divestment in science research, the so-called Tigers of Asia (Singapore, South Korea and Taiwan) continue to plow billions of dollars into the development of technical and research institutes. In the absence of renewed federal support for scientific research, what we might increasingly see is the return migration of many American-educated scientists and engineers. Such a scenario would signify a dramatic reversal in the direction of the scientific brain drain that historically has favored the United States.

Since at least World War II, foreign scientists have contributed to scientific advancement in the United States and our central position in the international scientific community. Many convincingly argue that to maintain this position in the context of a shortage of U.S. qualified scientists and increased global competition, especially from our Asian neighbors, research centers must have the means to recruit and appoint foreign scientists efficiently. The H-1B appears to be the best mechanism to achieve this goal.

Reorganization of High-Tech Work: Outsourcing Computer Programming

With the increased computerization of work, it is not surprising that we found both foreign and U.S. computer analysts

in various types of firms that cut across industrial categories. Foreign H-1B computer programmers and analysts and their U.S. counterparts whom we interviewed occupy positions ranging from low-level data entry positions in the petrochemical industries, to sophisti-cated software designers for high-technology MNCs. Assessing the role of these foreign workers in the U.S. labor market and their impact on labor dis- placement and U.S. wages is complicated by a number of major recent changes in the computer industry.

The organization of computer work has been changed dramatically and complicated by corporate downsizing and the increased demand for computer skills in all sectors of the economy. Many of the firms in which we conducted our field investigations, as might be expected from the history presented above, initiated dramatic downsizing during the late 1980s and early 1990s. Downsizing in the industries employing computer workers affected workers in different ways: many salaried workers were laid off permanently; computer consultants, who had worked for premium wages during the boom years of the seventies and eighties, faced wage depression resulting from an oversupply of computer workers and greater competition from outsourcing agencies.

We encountered a number of U.S. programmers and analysts who are out of work, mostly as a result of downsizing, not H-1B competition. These workers have not maintained the skill level required by advancing technology in today's computer industry. In many cases, they cannot afford the retraining costs. Thus, they are forced to compete with recent graduates with better skills or with foreign workers willing to work under the types of conditions that prevail in the industry today.[3]

Clients, Consultants and Job Shops

The way in which computer work is organized has become increasingly complex.

[3] Many displaced U.S. workers, unwilling to accept the possibility that downsizing has depressed wages, attribute declining opportunity and wages to foreign workers.

The key employers of foreign and U.S. computer programmers and analysts include: (1) client firms, large corporations that since the late 1980s advent of downsizing outsource the bulk of their software development, especially programming tasks; (2) consulting firms that have for several decades provided high-skill software development and application services to large corporations; and (3) outsourcing agencies or "job shops," new, but fast-growing competitors in this profitable and competitive labor market niche. In contrast to the high-skill services provided by consulting agencies, job shops appear to supply the client with a lower range of skills, primarily in programming and some software application.

In our firm sample, the clients typically were large petrochemical corporations that underwent considerable downsizing in the late eighties and early nineties. They employ only a small minority of highly-skilled H-1B engineers and software design specialists in their workplaces. Foreign and U.S. workers are recruited and paid on a competitive basis. We located several consulting firms that had serviced two of the client sample firms and one job shop that was a major outsourcing firm for the largest client in our sample. We interviewed workers, both U.S. and foreign, employed by these firms.

The computer consulting firms we studied in Austin and Houston provide services to client firms. They primarily use their own employees on a salaried or an hourly consulting basis and usually perform the work at the client site. The four consulting firms we studied primarily are involved in very advanced software design, production, and application. Two of these firms used to provide low-end software application services to client firms but claim that they are no longer able to compete at this skill level with outsourcing firms. We heard this story more than once. None are heavy users of H-1Bs although they employ a number of foreign-born, as well as U.S. analysts. The employers interviewed allowed access to current employees. Both foreign-born and U.S. workers are paid comparable high salaries or hourly consulting fees, depending on the arrangement made between the employee and employer; employers repeatedly commented that they try their utmost to find the best workers and pay

maximum wages regardless of a worker's nationality. Interviews with workers confirmed their employers' statements. Given that the firms we studied rely on highly-specialized skills in software design, employer recruitment and worker salaries remain very competitive. A more varied sample, including consulting firms involved in the low-end of software application, might yield very different results.

Large corporations increasingly have become clients of job shops. Downsizing in these large petrochemical and medical corporations has resulted in a reliance on both local consulting firms and outsourcing agencies to supply or perform that component of the production process that primarily requires low-level computer skills and does not require on-site supervision. The production processes in the information and research divisions of these firms do not require full-time, permanent employees. Often they need certain types of computer-related skills only on a temporary basis. These needs increasingly are filled by outsourcing agencies (job shops) that are the main employers of H-1B visa holders. Most of the work done by the H-1B workers is at the job shop, not the client site, which distinguishes them from consulting firms that are more likely to provide services at the client site. This a key distinction between the two service providers; job shops have a great deal of autonomy in structuring the work process.

As mentioned above, employers of two of the consulting agencies we interviewed claim to have been undercut by outsourcing agencies that pay lower wages to their employees and are able to bill their clients less without cuts to their own profits. Our interviews with U.S. computer programmers who work for clients under these various managements indicate that the current trend is towards increased reliance on the services of job shops. A small minority of U.S. workers recognize that the real employers in this computer game are the clients, i.e., the large corporations that use job shops to meet the needs of a flexible production process and, in some instances, as a dodge to avoid legal accountability. Managers in large corporations were proud to tell us that they employ very few H-1Bs, "only those with exceptional skills." Yet, this complex way in which computer work now is organized makes it very difficult to determine who truly employs computer work-

ers. We believe this is an extremely important issue, as the ultimate employer should be held accountable for the employment conditions of U.S. and foreign workers. To date, the media have focused on job shops—in fact, the suppliers—while ignoring the larger firms—the clients who create the demand for these low-level "production" type positions.

Sweated Labor at the Entry Level?

Job displacement and wage depression are potentially important issues within some parts of the computer industry. This is especially the case regarding lower-level programming and coding positions in job shops. Outsourcing firms employ both highly-skilled programmer analysts and low-level coders and programmers. Highly-skilled programmers work as salaried employees or contractors; in either case, H-1B worker earnings do not appear significantly lower than those of their U.S. counterparts. In contrast, we found a great discrepancy between the wages paid to foreign and U.S. workers in such low-level positions as coding, programming, and routine applications. We interviewed four H-1B worker programmers who were paid salaries almost $10,000 a year less than their U.S. counterparts in the same firm. Another job shop pays H-1Bs, who are on call for six days a week for one firm, salaries; they pay U.S. co-workers, who work at a variety of sites, hourly consulting fees. At neither place do the working conditions of the H-1Bs appear to meet those attested to by the employer, thus creating a two-tiered employment system in the industry. Further, these positions—that at most require a BA—do not involve the application of specialized skills that justify the temporary hiring of an H-1B worker. The following case illustrates our point.

We gained access to a job shop that was a major supplier of programming ser-vices for one of the largest clients firms in our sample. Most of its workers are Filipino computer programmers who were recruited abroad by the outsourcing firm's headquarters in New York. Word of mouth from other programmers lured these programmers to a well-known and quite fashionable Manila hotel where they all gathered in a seminar room and were "courted" by the recruiters—offered handsome salaries averaging $33,000 a year

with benefits (compared to $400-600 per month in the Philippines), a relocation fee of several thousand dollars, a one-way ticket to the U.S., initial housing, and the opportunity to lease a car through the company. In exchange, they had to sign a contract stating that they would work for the firm for a minimum of eighteen months, during which time the firm promised to petition for their permanent residence status.[4] None of the workers interviewed has received permanent certification, but they are reluctant to broach the subject with their employer for fear of loosing their job and, thus, their H-1B visa.

The Filipino programmers work in an underground, high-tech sweatshop, located on the basement level of the modern skyscraper in which the outsourcing firm is located. In the shop's front room, three Anglo supervisors sit at widely-spaced desks. In an adjacent back room of the same size, approximately twenty Filipino employees work in cubicles. All the H-1B Filipinos we interviewed at this outsourcing firm are on salary that they believe is at least $10,000 less than their American counterparts. This is difficult to determine precisely since the latter are sometimes paid on a consulting-fee basis. Consultant positions generally are more lucrative than salaried ones in computer work and also are more desirable because of the greater autonomy pro-vided to the workers. Nonetheless, the H-1B workers are willing to take less in earnings in exchange for the promise of a green card. For these workers, the H-1B definitely is seen as a pathway to permanent residency (even though some state that they plan to return to the Philippines). Upon receiving permanent labor certification, all workers intend to move out of this firm because of the poor working conditions and ambiguous policy decisions. Their most frequently cited reasons include too much supervision, a pattern of arbitrary promotions, and a practice of not paying workers for overtime. They complain that, while American workers always go to the client's site, foreign workers rarely do so. On those few occasions when they are sent to the client's site, they told us, they typi-

[4] This was the time required for the initial cohort of recruits; subsequent cohorts had to promise to work anywhere from two to three years.

cally are accompanied by an Anglo employee who interfaces with client representatives.[5]

The H-1B workers also feel that their jobs could be done by U.S. workers. The majority told us that their previous work experiences or skills used in the Philippines are not applied in their positions at this outsourcing firm. In one case, a worker, who was recruited with the understanding that she was being hired because of her skills in COBALT programming, has been with the job shop for two years and has never used these skills. On the contrary, the firm trains the foreign workers; the majority of these workers claim they learned entirely new skills to fit clients' needs. At the same time, these Filipino workers see themselves as more desirable than other foreign workers because of cultural similarities, including English fluency and colonial linkages. In summary, the possibility for abuse of H1-B workers exists in these low-level computer positions. Moreover, at least in the case of Houston, the market has not provided training and employment opportunities for U.S. workers structurally displaced by downsizing strategies. Our findings suggest that, in cases where firms (all types) use outsourcing agencies for low-skill level computer programming and coding, the potential for wage depression and some job displacement may exist.

Policy Recommendations.

I. Given the increasing globalization of scientific research, coupled with the enormous contributions foreign scientists have made to U.S. research institutions, we recommend that efforts be made to facilitate temporary positions in these settings. Specifically, we recomend:

- **Creation of a special H category for research universities and institutes.** This category should not have a numerical cap to assure the

[5] As these foreign workers come into contact with their U.S. counterparts in the industry, they express increasing interest in becoming contract workers, positions seen as more lucrative and autonomous than salaried positions.

continued entry of high-level foreign scientists into research institutions. Creation of this category could make thepaperwork process less cumbersome for institutions' administrative personnel, usually the Direc- tors of International Services[6] who have little training in immigration procedures and less burdensome for foreign workers, especially postdoctoral fellows.

II. Corporate downsizing has had an impact on American workers' earnings and job security. Nowhere is this more observable than among workers in computer-related occupations. Downsizing and the use of temporary workers is increasingly observable in other industries as well. While it is impossible to turn the tide of market forces, a few suggested changes could minimize the potential for the abuse of the H-1B worker and for the negative impact of restructuring on American workers, specifically computer programmers and analysts:

- **The U.S. Department of Labor should monitor closely the supply of U.S. workers in low-level computer positions.** In the absence of a real occupational shortage, perhaps the educational requirements for H-1Bs should be increased from a bachelor's to a master's degree. We found that it was H-1B workers with less training who are most likely to face workplace abuse. Clearly, there are special skills and techniques that highly-skilled foreign workers possess. We have, however, come across too many foreign H-1Bs with only bachelor's of science degrees who are performing tasks that can be easily done by U.S. workers.

- **Emphasis should be given to retraining unemployed workers who are displaced during corporate downsizings.** In the absence of federal funding for this retraining, we recommend giving tax breaks to unemployed U.S. com-

[6] In Texas, the Attorney General's Office does not allow public institutions to hire lawyers for this purpose.

puter workers to help support their personal retraining costs.

- **The client company, as well as the outsourcing agency, should be held accountable for the working conditions or violations of the terms of the H-1B visa.** The abuse of H-1Bs is most prevalent in the joint ventures of client and outsourcing firms. Greater regulatory efforts on the part of the Department of Labor could track the employment history of firms, not industries, to capture the effects of downsizing and corporate leasing of services on U.S. workers.

Conclusions

Given what looks like a robust labor market in Houston for computer analysts and programmers and for high-level researchers in faculty positions, we initially were at a loss to explain what we encountered in the field: unemployed and underemployed computer programmers and analysts and an increasingly tight labor market for faculty positions. We also were perplexed by professional association reports of increasing unemployment among scientists, engineers, and computer analysts. The only way to explain what looks like a simultaneous surplus (unemployment) and shortage of workers (projected demand) is by the increasing prevalence of spot shortages in particular high-skilled occupations within science and technology. Unfortunately, we were unable to locate any objective data to illustrate clear instances of spot shortages resulting from an uneven mix of supply and demand.

What we did encounter in the field, however, were displaced older computer analysts who were not retrained to compete in this rapidly changing technological environment and unemployed computer analysts who would not work for wages less than they had received during the boom years. At the same time, we also encountered employers scraping to locate competent computer analysts to work with an emergent complex computer language such as C++. Similarly, we came across positions at universities that had gone unfilled for months or years because the department was looking for someone with

a particular skill, e.g., an engineer skilled in robotics development.

These seemingly contradictory and divergent employment trends among skilled workers are not so perplexing once we look beyond immigration policy and focus on the implications of corporate downsizing and global labor markets for skilled workers. While corporate downsizing in Texas cut across all industries, it had particularly severe consequences for computer programmers, system analysts, and engineers employed in the research and development and information services divisions of many large petrochemical firms headquartered in Texas. These skilled workers, many of whom had carved out their own niches in the petrochemical industry and were commanding unprecedented high salaries during the oil boom years of the seventies and eighties, found themselves either unemployed or unable to command their previous consulting fees. Although the Texas economy has taken a turn for the better in recent years, skilled workers encounter much greater competition than before as a result of a burgeoning consulting sector that increasingly services client firms. Faced with increasing competition and stagnant wages, many disgruntled workers target the H-1B program as the source of their problems.

This is not to say that corporate downsizing alone is responsible for the displacement and wage depression of skilled computer programmers and analysts in Texas labor markets. The growth of the consulting sector in Texas labor markets also has created greater competition among these skilled workers. Within this sector, some consulting firms capitalize on the H-1B program to bring in foreign workers to perform entry-level tasks that could be done by native workers with a bachelor's degree.

The recruitment and employment conditions of skilled H-1B workers in science and research operates at a very different level. Candidates for these high-level research positions are carefully recruited on a competitive basis and paid the prevailing wages. In these research settings, the H-1B program achieves its intended policy goal, providing employers with immediate access to the best and brightest among an international labor pool of

highly-qualified scientists and researchers.

While the focus of this study is limited to the recruitment and employment experience of engineers, computer programmers, and scientists and researchers in less than thirty firms in Texas, the findings strongly suggest a more general trend. Despite an apparently "robust" Texas economy with a high demand for technical and professional workers, the labor market opportunities for most will remain limited. The most qualified and most experienced segment of the workforce will be the most prepared to escape the consequences of increased restructuring of the workplace. They are the ones most able to take advantage of the demands and opportunities of a dynamic global market that increasingly is driven by rapid research advances in technology and science requiring new, specialized skills. Slight increases in the number of temporary foreign workers in U.S. labor markets, as provided by the H-1B visa, appear to have little effect on these structural changes in the organization of work. Further restrictions and regulations in skilled immigration, however, might well have dramatic effects. Restricting employer access to temporary skilled foreign labor might expand U.S. corporate offshore production to include highly-skilled production in recently established research sites in Asia and elsewhere. Extreme caution must, therefore, be exercised when contemplating changes to existing policy.

NONIMMIGRANT VISA PROGRAMS: PROBLEMS AND POLICY REFORMS

GREGORY DEFREITAS

HOFSTRA UNIVERSITY AND RUSSELL SAGE FOUNDATION

Any attempt to improve this country's nonimmigrant policy first must be clear about the basic purpose of that policy within the broader context of the national immigration system. The principal goal of the immigration system has, for at least thirty years, been the humanitarian one of reuniting families and providing safe haven to refugees. Some have argued that this emphasis has been excessive, resulting in declines in the skill levels of recent cohorts and in worsening competition with native workers. They favor making economic characteristics of prospective immigrants a much more important criterion for admission.

As an economist, I find such proposals tempting but ultimately wrong-headed. My own research and reading of the latest empirical literature convinces me that immigration has, at least at current levels, had relatively small net impacts on overall domestic wages and employ-ment (DeFreitas 1995). This does not lead me to favor unrestricted admissions, nor does it mean that we should neglect to evaluate carefully and be ready to make adjustments for the economic impacts of future migration streams.[1] But humanitarian goals remain far preferable to any strategy (probably futile) of making immigration another lever of economic policy. In the event that proposed reductions in annual entry slots are enacted in the near future, it seems to me far more important to preserve ample family and refugee visas than to earmark scarce visas based solely on an applicant's occupational skills.[2] Moreover, a basic national

[1] I have detailed my recommendations for reforming the permanent resident visa system elsewhere (DeFreitas 1995).

[2] See the findings of Jasso and Rosenzweig (1995) on the reduction in the occupational differences between employment-based and family-sponsored immigrants within a few years of arrival.

employment goal should be eventually to fill any short-term skill shortages through training or retraining of native workers rather than relying on foreign professionals.

Since most economic research has focused on the impacts of immigration on unskilled or semiskilled labor markets, relatively little is known about the domestic consequences of importing large numbers of skilled workers. We do know from the 1990 census that more than one-tenth of U.S. scientists and engineers are foreign born, well above the immigrant share of the population (Bouvier & Simcox 1995). There are more immigrants in professional occupations (1.35 million) than there are African American professionals (1.1 million). And it is clear that well-educated immigrants have carved out niches in certain well-paid occupations. For example, more than one-fifth of U.S. physicians are now foreign born, and the fraction is much higher in such specialties as immunology, neurology, and pediatrics. About 12.3 percent of all engineers are immigrants, with a disproportionate foreign presence in education and in private research and development. The foreign born account for 9 percent of registered nurses, of whom nearly one-half are from a single country, the Philippines. In New York City, it has been estimated that 20 to 30 percent of nurses are temporary foreign workers (U.S. DOL 1989). Even in the government sector, there is evidence of ethnic networks insulating immigrant niches. In New York City government in the 1980s, the foreign born achieved growing concentrations in technical professions, with competitive equivalents in the private sector, such as accountants, chemists, and engineers. Nearly one-half of all new engineers hired by the New York Transportation Department in the period 1986-1990 were Asians (Waldinger 1994). Immigrants appear to be attracted to secure, well-paid, public sector jobs, at least until they can improve their language skills enough and attain the licenses required to enter the private sector.

The studies of immigrant professionals typically conclude that their rising share of high-level jobs may induce employers to become dependent on foreign labor sources instead of actively recruiting and training natives for these jobs (see: Levine, Fox & Danielson 1993; National Research

Council 1988; U.S. DOL 1989; Waldinger 1994). Insofar as this diminishes natives' access to high-skill, high-pay jobs, the implications for American workers at all skill levels are worrisome. For it may mean that not only is there competition between native- and foreign-born professionals, but also that there is some reduction in the chances of the less-skilled for upward occupational mobility. Until more research becomes available on this issue, it seems prudent to, at a minimum, resist any attempts to expand the number of employment-based permanent resident slots or even to lower the number somewhat.

Nonimmigrant policy reform becomes all the more important as the immigration system undergoes change. The non-immigrant programs need to meet three goals: (1) to provide American busi-nesses, universities, and cultural institutions access to international talent; (2) to provide foreign visitors access to U.S. schooling and training; and (3) to ensure that pursuit of the first two goals does nothing to expose U.S. workers to unfair competition with foreigners or to reduce their opportunities for training and upward job mobility. In what follows, I briefly discuss some of the main reasons why certain current non-immigrant programs are failing to serve these ends and make a number of recommendations for policy reforms.

THE H-1B PROGRAM

H-1B temporary visas for specialty occupations have been the source of great concern of late for a number of reasons. First, it presently is completely legal for employers to lay off U.S. workers and replace them with H-1B workers. As recent corporate restucturings, global competition, and defense cutbacks have threatened the job prospects of many American technicians and professionals, more and more cases of alleged displace-ment by temporary foreign workers have appeared. For example:

- Aggressive downsizing at Digital Equipment Corporation slashed nearly 21,500 jobs between late 1991 and November 1993. But, this coincided with the firm applying for more than 1,100 H-

1B visas to bring in foreign computer workers.

- In June 1995, at CSX Corporation's Sealand unit in New Jersey, about 100 American computer programmers lost their jobs as Sealand hired an equal number of replacements from India and the Phillipines. Worse still, the U.S. workers were required to spend their last weeks at the firm training their own replacements. Many of these jobs ultimately will leave the country with the newly-trained foreigners on their planned return home. Sealand estimated that the export of jobs would save the company 30 percent on salaries (Zachary 1995).

- Likewise, American International Group, Inc. recently laid off almost 250 computer service workers in its insurance operations in New Jersey. H-1B replacements were brought in and received their training from the soon-to-be-terminated U.S. employees.

A second source of concern with the program is the apparently widespread abuses by so-called "job contractors." Some of these (such as Syntel Inc., provider of the replacement workers to American International Group, Inc.) are alleged to bring large numbers of foreign workers into the country solely to lease them to U.S. firms. They appear to shuttle these workers in and out of the country, especially to fill many computer and health care jobs. The Department of Labor [DOL] has documented numerous cases of job contractors violating the law by paying foreign workers far below the prevailing wage. In the physical and occupational therapy fields alone, nearly 400 H-1Bs recently were found to be owed $2 million in back pay by contractors.

The relative ease with which unscrupulous job contractors have exploited the program highlights another problem. Employers are not required to show that U.S. workers are unavailable for the jobs H1-B workers will fill, nor are employers required to demonstrate that they are seeking to train or recruit Americans for these jobs. In fact, the program is driven largely by employers themselves.

Finally, any program that is supposed to meet only "temporary" employment needs should keep foreign worker stays as brief as possible. Yet, current law allows for a period of stay of as many as six years, well beyond any reasonable notion of a temporary visit to fill a short-term skill shortage. This likely induces some firms to become dependent on a steady supply of foreign workers rather than to seek to recruit natives. Moreover, it is evident that H-1B visas have become a conduit for obtaining employment-based green cards. DOL estimates that more than 90 percent of the recipients of such green cards are already in the U.S. and that perhaps two out of three of these are already employed (often illegally) by the very firm that files the immigrant petition for them.

These problems lead me to suggest the following changes in the H-1B program. Some of these correspond to recent proposals by the commission and by DOL (Fraser 1995; Reich 1995), but, in general, I favor stronger measures.

Recommendations

1. Restrict the eligibility for H-1B visas to those occupational categories in which DOL verifies that there is a labor shortage. This would require a new system parallel to the existing labor certification program. The latter long has been far too employer-driven and inefficient, as the DOL itself now recognizes. Hence, the new system must be designed carefully to avoid these past flaws and to exploit better both govern-ment and independent economic analysis of local labor market conditions. More resources need to be allocated to improve the avail-ability of up-to-date labor market data for localities, particularly that subset in which most temporary foreign workers tend to concentrate.

2. Reduce the validity period of labor condition applications [LCAs] from six to two years and bar renewal applications. Under recently adopted DOL rules, the validity period for each application was cut to three

years, but employers are still allowed to keep an H-1B worker for a total of six years if they submit an LCA for a three-year renewal. Anything more than two years is excessive and encourages some employers to become dependent on foreign labor.

3. Require that all employers filing H-1B LCAs attest that, within the six months before an H-1B worker begins employment, they have not laid off legal permanent resident aliens or U.S. citizens with similar qualifications and work experience in the job for which the temporary foreign workers are being sought; and require that they attest that they will not lay off such legal immigrant or citizen workers within the six months after H-1B employees are hired or leased by the firm and for the duration of the visas.

4. Bar access to H-1B workers where a firm's employees are involved in a labor union election campaign, strike, or lockout. The DOL now supports prohibitting access to such workers during strikes or lockouts, but protection of workers' democratic right to choose collective bargaining representation without interference by their employers also necessitates guaranteeing, once employees have filed an application for an election to choose whether or not to be represented by a union, that foreign workers not be used as a real or perceived threat.

5. Require employers filing H-1B LCAs to demonstrate that they are undertaking substantial and continuous efforts to fill the jobs for which they currently desire foreign workers with U.S. employees in the near future.

6. Require employers of H-1B workers to pay a fee, equal to 20 percent of the value of the total compensation package it will pay to those workers, into a public or private fund certified by the DOL as dedicated to the goal of improving the training and recruitment of U.S. workers into the occupations for which the H-1B workers currently are being employed. This parallels the proposals of the commission for employment-based immigrants.

7. Raise the standards to be met by "job contractors" to prevent past abuses at any of the multiple work sites that may lease their H-1B workers. Current DOL regulations generally are limited to the place of employ-ment at the time an employer files an LCA. This allows job contractors who place foreign workers with other employers to enjoy laxer controls. The new policy reforms recommended above should be applied to all work sites where H-1B nonimmigrants are working, wheth-er or not they are employed by a job contractor (see discussion in U.S. DOL 1993).

8. Require nonimmigrants holding H-1B visas to leave the U.S. for a minimum of one year following expiration of that visa and before applying for any permanent resi-dency visa. This will help end the common practice by which H-1B visas are used merely as a holding mechanism while nonimmigrants stay in the U.S. seeking receipt of green cards. It also should help reduce U.S. employers' dependence on nonimmigrant labor.

OTHER EMPLOYMENT-BASED NONIMMIGRANT PROGRAMS

The wide array of other temporary visas granted for ostensibly employment purposes also bring into the country large numbers of individuals. For example, J-1 visas (for exchange visitors to teach, study, or conduct research) totaled more than 197,000 in FY 1993, and another 43,000 relatives came with them. To coordinate all these programs so as to protect American workers better, I suggest:

9. All other employment-based nonim-migrant visa applications must pass the same labor shortage test recom-mended [see 1 above] for H-1B LCAs before the nonimmigrant is permitted to work here during the duration of the visa.

CONCLUSIONS

Widespread concern about the nation's worsening income inequality and under-employment have generated renewed debate about the optimal volume and composition of immigration. Thanks to fierce lobbying by business groups and encouragement from econo-mists claiming immigrants' "quality" had fallen, the U.S. government in the 1990s expanded the permanent visa category for people with "needed skills" and granted large numbers of employment-based nonimmigrant visas. This was done with very little research knowledge of the possible consequences on skilled native workers or on the prospects of the unskilled for occupational mobility.

There is evidence that skilled immigrants recently have been hired by firms that were simultaneously cutting their skilled native work force. And many on H1-B temporary visas, after mastering key elements of the work process at U.S. firms, return home to train others to do the same work. This then facilitates the export of jobs abroad by American firms seeking low-cost, high-tech labor. Computer programmers, cinematog-raphers, and aircraft machinists appear to be among those most at risk of replacement. So great has their concern become that it has helped spark at least one strike (Boeing) and led the DOL to undertake a long-overdue scrutiny of the abuses of some job-contracting firms.

These modest steps have provoked an opposition campaign by the National Association of Manufacturers, the U.S. Chamber of Commerce, Microsoft, and other computer companies. They insist that global firms need large numbers of skilled foreigners to stay competitive and grow, thereby enabling them to expand their U.S. base. However, in an era of widespread corporate downsizing, claims of skilled labor shortages have raised growing suspicions. Unlike the early 1980s, the majority of permanent layoffs now are occurring among college-educated employees. The share of job loss accounted for by those earning at least $50,000 has doubled since the eighties. Many scientists, engineers, and computer specialists have found themselves quite vulnerable to cutbacks by defense contractors, high-tech civilian firms, and universities.

What is needed now is more, not less, limitation on and monitoring of skill-based temporary immigration programs. International exchange of ideas and skills still can be ensured by granting brief visas for foreigners willing to train U.S. workers. And the more than 300,000 student visas now granted each year provide ample opportunity for those from abroad seeking access to training here.

Instead of exporting more high-wage jobs or importing professionals to meet supposed "skill shortages," business and government must be induced finally to provide first-class schooling, training, and retraining for the vast numbers of low-wage and underemployed Ameri-cans. And, as well, they must help generate enough new high-wage jobs for these workers to fill.

CALIFORNIA'S FARM LABOR MARKET AND IMMIGRATION REFORM[1]

PHILIP MARTIN
UNIVERSITY OF CALIFORNIA—DAVIS

Agriculture in California has from its beginnings relied on newcomers to the state who had few nonfarm job options to seasonal farm work. For this reason, the state's farmers long have had a keen interest in U.S. immigration policies, usually seeking exceptions to general U.S. immigration policies on the grounds that the nature of California agriculture was such that foreign workers were needed.

Since 1980, California agriculture's most successful influence on immigration policy was reflected in the Immigration Reform and Control Act [IRCA] of 1986. IRCA imposed sanctions or fines on U.S. employers who knowingly hired unauthorized alien workers and offered legal immigrant status to many illegal aliens who worked in U.S. agriculture. The intent of IRCA was to deter illegal immigration, to legalize the status of long-term illegal U.S. residents and illegal farm workers, and to regulate the access of farmers to legal nonimmigrant and probationary immigrant workers. Growers were able to win concessions for because IRCA threatened to stem their flow of labor. The long-standing H2-A program was simplified and a guestworker program, contingent upon a reduction in the supply of labor, was instituted.

More recently, Congress has moved to further strengthen border patrol efforts, as well as sanction enforcement. As a result, and despite strong statements against agricultural guestworkers in June

[1] I am indebted to Patrick Ramsey for research assistance in mailing and tabulating the employer survey.

1995 by both President Clinton and the Commission on Immigration Reform, California farm organizations tried and failed to include a guestworker program in immigration reform legislation moving through Congress. As in the mid-1980s, the growers argue that, despite employer sanctions and high unemployment rates among U.S. farm workers, at least 30 to 50 percent of their seasonal workers are unauthorized. If effective, strengthened border enforcement sanctions might, they believe, remove these workers.

They argue a guestworker program, one that is flexible and easy to administer, will be necessary in order to make their needed worker numbers and to meet legal requirements for authorized status.

CALIFORNIA AGRICULTURE'S LABOR MARKET

California has the nation's largest and most diverse agriculture. California farmers produce the same commodities that are found in other states—milk, wheat, and cotton—but the distinguishing feature of the state's agriculture is the production of specialty crops: California produces about 40 percent of the nation's fruits and nuts, vegetables and melons, and such horticultural specialties as flowers and mushrooms. These so-called FVH commodities, in turn, represent one-half of California's $20 billion in farm sales, and the orchards, vineyards, and greenhouses in which they are produced are where most farm workers find jobs.

There are many ways to describe a California farm labor market in which 800,000 to 900,000 individuals find at least temporary jobs with 25,000 crop and livestock employers or agricultural service firms, such as farm labor contractors and custom harvesters. One way is to focus on three "C"s: concentration, contractors, and conflict.

Concentration refers to the fact that most farm workers are hired by a relatively small number of large farms. Contractors refers to the presence in many farm labor markets of "intermediaries" who match seasonal workers with jobs. Conflict refers to the stormy history in which workers protested low wages or poor

working conditions but then individually got out of agriculture when their collective efforts to obtain wage and benefit improvements were rebuffed.

Concentration. Agriculture is probably California's largest employer of adult immigrants. According to state Unemployment Insurance [UI] tax records, 24,500 California farm employers paid $4.6 billion in wages to employees in 1990 (Martin & Miller 1993:22). But these farm labor data conceal as much as they reveal. Most of these farm employers or "reporting units" are small; one-half pay less than $10,000 in farm wages. The largest 1,250 farm employers—just 5 percent—pay about two-thirds of California's farm wages.

Concentration is also the rule among farm workers. A "farm worker" is anyone who works for wages on a farm. Farm work is seasonal, and so most farm workers also do nonfarm work or, as many are immigrants, return to their country of origin when there are no farm jobs for them in California. Most workers are in the farm work force for only a short time. More than one-half have less than $1,000 in annual farm earnings which, at $5 hourly, means that they do 200 or fewer hours of farm work, or the equivalent of 5 weeks.

Concentration means that the largest 5 percent of employers, and the 10 percent of farm workers who are employed year-round, account for most of the farm wages paid and earned. The "average" farm employer is very small, while the large farm employers, who hire most of the state's farm workers, each may employ a peak 5,000 workers and have a weekly payroll of $1 million—making them large employers by any definition.

In **Figure 1**, small farms were those that sold less than $50,000 of FVH commodities in 1992—they were 61 percent of all production units, but they accounted for only 3 percent of total sales. At the other extreme, the 39 percent of FVH farms that each sold more than $50,000 of FVH commodities in 1992 accounted for 97 percent of California's FVH sales.

The "average" California farm worker earned about $3,000 from farmers in 1990, but there are few workers with such earnings. Instead, workers tend to fall in to

one of three groups (Martin & Miller 1993). Just more than one-half are very low earners—earning $1,000 or less for working on one or more farms for a few weeks during the year. About 40 percent, or 360,000, are in the seasonal worker category, earning $4,000 to $6,000 for one-half year's farm work. The third group are the year-round workers who earn $12,000 or more annually.

Who are these large farm employers who hire most of the state's farm workers? A 1992 survey of 900 California farm employers reported that only about 30 percent of all farm employers were corporations, but 60 percent of the sample farms with annual payrolls over $500,000 were corporations, usually family-run (Rosenberg, et al. 1995:14a). An example is the Zaninovich table grape farm in California's San Joaquin Valley, an operation that annually sells about 5 million 25-pound boxes of grapes at an average price of $10 per box; Zaninovich hires 1,000 farm workers to help generate $50 million in annual grape sales.

Fresno-area raisin farms represent the small end of the farm size spectrum. In the most labor-intensive activity in U.S. agriculture—some 50,000 farm workers spread through 200,000 acres of vineyards to cut bunches of 20 to 25 pounds of green grapes and lay them on paper trays to dry into raisins for six to eight weeks each August and September. Workers receive $0.15 to $0.18 per paper tray of raisins cut and laid, and the farm labor contractor [FLC] who typically recruits them receives $0.04 to $0.05 for payroll taxes, business expenses, and profits. Most of the vineyards are small—twenty to fifty acres—and workers are often "recruited" with a sign at the entrance to the vineyard saying, in Spanish, "workers wanted."

Workers employed in short harvest crops such as raisins can earn more if they find other farm jobs, such as harvesting peaches and plums before, and olives and citrus after, the raisin harvest. Many farm workers are able to string together a series of farm jobs, but it is not easy for many of them to travel from farm to farm looking for work.

Contractors. Intermediaries who find jobs for farm workers and supervise them while they work, are the second "C" of the California farm labor market; most farm workers find a succession of farm

jobs with the help of a contractor intermediary. Contractors are not a new phenomenon; Chinese farm workers in the 1870s designated one person in the crew who could speak English to search for the next farm job for the crew. Over time, farm labor intermediaries evolved from one of the crew to independent businessmen who seek to profit from the difference between what a farmer pays to have a job done and what the worker gets (Fisher 1952; Fuller 1942; McWilliams 1949).

Contractors have been the major farm labor story of the 1980s and 1990s. There were only 935 FLCs in California in 1990 who were registered with state Unemployment Insurance authorities to pay taxes on the wages they paid to workers, but they employed one-third of all farm workers reported to the UI system, and their role in matching farm workers and jobs has been increasing (Thilmany 1995).

Critics assert that there are far more FLCs who are not registered and that farmers have encouraged the rise of labor contracting by switching from hiring workers directly to hiring them through hard-to-regulate contractors. According to farm worker advocates, farmers know that these "merchants of labor" must be cheating the government or the workers, as the FLCs in some cases agree that their workers will do farm work for what appears to be a money-losing fee. Cesar Chavez made the elimination of farm labor contractors one of keystones of his efforts to reform the farm labor market and ensured that the California Agricultural Labor Relations Act [ALRA] in 1975 included a clause that asserted that FLCs could not be employers for labor relations purposes.

The theory was that only such strict farmer liability for FLC labor relations law violations would encourage farmers to be responsible for the activities of FLCs who bring workers to their farms. Many farm worker advocates would like to impose strict liability on farmers for minimum wage and immigration law violations. Under current circumstances, a FLC can be the employer solely liable for minimum wage and immigration law violations, but not for labor organizing violations.

Conflict. The third "C" is the inevitable conflict between employers and workers over a "fair" wage. This conflict can be resolved in three major ways: first, by em-

ployers acting unilaterally, as happens in workplaces where the employer says, "Do it my way or leave;" second, by determining a fair wage through collective bargaining; and third, by using government rules that stipulate minimum wages and mandatory benefits for workers. The usual way of resolving workplace conflict in agriculture has been for dissatisfied workers to exit the farm workforce.

Conflict in farm labor markets has several unique characteristics. Farm employers often band together and set a "standard" wage, thus creating peer pressure to resist worker demands for higher wages or they decide not to use the H-2A program to "prove" that it cannot work in California. In many instances as farm worker leaders have been radical outsiders in conservative rural communities, the entire community, not just the farmers, often was willing to tolerate violations of individual rights to resolve "farm labor troubles." The workers who were dissatisfied with the wages they were offered on farms sometimes faced eviction from their temporary homes, making their choice about whether to refuse to work a decision that affected both their income and their housing.

California Fruits and Vegetables

California has led the nation in farm sales since 1950. While the state has only 2 percent of U.S. farmland; it accounts for more than 10 percent of the nation's farm sales because it produces high-value fruit and vegetable commodities. Thus, California farmers obtain far more revenue per acre than most U.S. farmers. For example, California harvested 1.2 million acres of vegetables and melons in 1990, and they had a farm value of $3.5 billion. Nebraska farmers, by contrast, tilled fifteen times more land but had only about the same level of farm sales.

U.S. agriculture can be profiled as an economic sector producing mostly livestock and field crops. California agriculture is different. About two-thirds of California's 1994 farm sales of $20 billion represents the sale of crops; only one-third represents the sale of livestock products. Within California's crop sector, fruits, vegetables, and horticultural specialties worth $9 billion were three-fourths of the state's $12 billion in crop sales. Field crops, such as cotton, hay, wheat, and rice, are important users of California farm

land and water, but they account for only one-sixth of California's farm sales.

California began producing labor-intensive fruits and vegetables and shipping them long distances a century ago, but much of the expansion of California's FVH agriculture occurred since World War II. In some cases there have been truly dramatic production increases: broccoli production grew more than sixfold between 1960 and 1993; almond and strawberry tonnage rose more than fivefold; nectarine and wine grape production more than quadrupled.

The land used to produce fruits and vegetables is valuable. In 1990, for example, land in the Monterey area used to produce vegetables was worth an average $10,000 per acre and vineyards and orchards in the Fresno area sold for $5,000 or more per acre. A rough indicator of the amount of money tied up in California FVH agriculture can be seen in the following estimates: if the value of CA vegetable land averages $10,000 per acre, then 1 million acres of California vegetable land is worth about $10 billion. If the value of fruit and nut land averages $5,000, then 2 million acres of fruit and nut land also is worth $10 billion.

Labor Costs and Harvest Cycles

Most of the fruits and vegetables grown in California generate farm sales of $2,500 to $3,000 per acre. The production of fruits and vegetables is considered "labor-intensive," an adjective that is rarely defined but suggests that the costs of hired workers are the single largest production expense. Labor costs in FVH production range from 20 percent to 50 percent of total production costs—higher than the 20 percent average in manufacturing, but less than labor's 70 to 80 percent share of costs in many service industries.

In most commodities, expenditures for hired workers—seasonal and year-round, and production plus supervisory labor—are about one-third of total production costs. A farmer grossing $3,500 per acre from the sale of table grapes pays about $1,500 to the workers who tend and harvest them. From the point of view of consumers, labor costs are only a small fraction of supermarket prices. In the early 1990s, farmers got about $0.40 per pound for table grapes and $0.13 represented the cost of labor. However, the retail price of grapes averaged $1 per

pound, so that farm worker wages represented only about 13 percent of the retail price.

If farm worker wages were to double, if farmers continued to use the same amount of labor as before, and if all of the increased cost of farm labor was passed on to consumers, then the typical wage of grape workers would jump from $6 to $12 hourly. However, the cost of grapes for consumers would rise only 13 percent, to $1.13 per pound.

Labor costs, important to farmers, are much less important to consumers because farmers obtain only about one-third of the typical retail price of a fruit or vegetable. Thus, whether farm worker wages go up or down, they affect only one-ninth of the retail price of a fruit or vegetable.

If farm worker wages were to double, as in the above example, experience shows that most of the adjustments on the farm would take the form of a reduced demand for workers, not an influx of U.S. workers into the farm workforce. If wages were higher, farmers would have incentives to find substitutes for farm workers. Perhaps they would use machines to harvest their crops, even if the machine did not pick as carefully as farm workers.

In other cases, farmers might not pick as often or, to make workers more productive, farmers might develop mechanical aids for them. In some cases, higher wages might lead to importing a commodity from a lower-wage country. In short, rising farm worker wages would cause far more changes in the way farmers get work done than in the prices consumers pay for food.

California fruits and vegetables do not ripen uniformly, so the peak demand for labor shifts around the state in a manner that mirrors harvest activities. **Figure 2** provides one estimate of the seasonal pattern of employment on California farms.

Harvest activity occurs year-round, beginning with the winter vegetable harvest in southern California and the winter citrus harvest in the San Joaquin Valley. But the major winter activity is pruning—cutting branches and vines to promote the growth of larger and more uniform fruit. In fruits such as peaches, pruning accounts for 10 to 20 percent of the seasonal labor required

to produce the fruit but, because pruning occurs over several months, there are fewer workers involved. During the rainy months between November and April, employment on farms is only one-half its peak September levels.

Surveys find a declining percentage of migrant farm workers. A 1965 statewide survey of farm workers found that 30 percent migrated from one of California's farming regions to another; a 1981 survey of Tulare county farm workers found that 20 percent had to establish a temporary residence away from their usual home because a farm job took them beyond commuting distance (California Assembly 1969; Mines and Kearney 1982). A national survey of farm workers in the early 1990s found that fewer than 10 percent followed the ripening crops (Gabbard, Mines & Boccalandro 1994).

There is some worker migration between farming regions organized by employers, such as the lettuce harvesters' move from Salinas to Imperial to Huron, but such employer-organized migration seems to be decreasing. Instead, a lack of housing and surpluses of labor everywhere have discouraged the migration of workers from one farming region to another. Farm labor contractors continue to move crews of solo men from area to area, but there are now far fewer "free-wheeling" families travelling up and down the state looking for farm jobs without prearranged jobs and housing than in the 1960s and 1970s. Workers tend to stay in one area of California for three reasons: the harvesting of some crops has been stretched out for marketing and processing reasons; temporary housing for migrants is scarce; and the availability of unemployment insurance and service programs makes migration less necessary.

Many workers still migrate, but they tend to shuttle into the U.S. from Mexico and then remain in one location rather than to follow the crops after their arrival in California (U.S. Department of Labor 1993a; 1993b). Thus, the reduction in follow-the-crop migration does not mean that there is no migration, only that the nature of migration has changed. In theory, migrant camps open for six months annually should experience considerable turnover as families move on to the next harvest. That they do not highlights the importance of housing—the lack of it—in explaining behavior: once a "migrant fam-

ily" finds suitable housing, it is reluctant to move out and have to search again for housing.

Farm Employment

California farmers employ about 900,000 individuals to fill an average 350,000 farm jobs over the year. Total and average employment have been remarkably stable since the mid-1960s as mechanization that eliminated farm jobs has been offset by expanded production and the switch from farm families to hired workers to do more of the state's farm work.

Mechanization—picking a crop by machine rather than by hand—has reduced employment in many commodities, but the production of other commodities has expanded enough to create new jobs and to stabilize farm employment (Brown 1984). Processing tomatoes provides an example of what happens to farm worker jobs as a result of mechanization (Thompson & Schering 1978). In 1960, a peak 45,000 workers—80 percent of whom were *braceros*—handpicked 2.5 million tons of the processing tomatoes used to make catsup in California.

In 1990, about 5,500 mostly female farm workers were employed to sort four times more tomatoes. (Mamer & Wilke 1990). In this case, mechanization reduced the number of jobs for farm workers and changed the harvesting task from hand-picking tomatoes into field boxes to riding on a machine and sorting machine-picked tomatoes.

During the 1960s, many thought that the choice was to mechanize or stop growing hand-harvested crops (Thomas 1985). For example, a major 1970 study predicted that "California farmers will continue the intensive search for labor solutions, particularly mechanical harvesting" (Dean, et al. 1970:52). Another 1970 study concluded that "the door to employment is rapidly closing for those persons whose only qualifications for employment are a will to work and enough muscle to compete" (Cargill & Rossmiller 1970:22).

The expectation that soon there would be no need for those who could bring only strong backs to farm work was so widespread that the federal government began programs to help farm workers adjust to the nonfarm jobs they, it was expected, soon would have to seek (Martin & Mar-

tin 1994). But the mechanization of the tomato harvest proved to be the exceptional type of labor-displacing change in California agriculture, not the rule.

The publicity, generated in the late 1970s by lawsuits against the University of California for its part in using tax dollars to develop plants and machines that displaced farm workers, reinforced the false sense that soon there would be no need for seasonal farm workers (Martin & Olmstead 1985). In reality, the surprise is how little labor-saving mechanization there has been in California since the 1960s. In 1990, most of the major fruits and vegetables grown in the U.S. were hand-harvested.

There have been important labor savings in California agriculture, but they are usually less visible than machines replacing hand-harvesters. Changes in production practices for perennial crops have saved labor—such as drip irrigation that saves irrigator labor, dwarf trees and vines trained for easier hand or mechanical pruning, and precision planting and improved herbicides that save thinning and hoeing labor.

As machines and changes in production practices eliminated some jobs for farm workers, there was an important counter trend creating jobs for field workers: field packing. Crops traditionally have been picked by field workers into bins or boxes and then hauled to a packing shed, where nonfarm workers sorted, graded, and boxed the table grapes and broccoli. During the 1970s and 1980s, many crops began to be picked and packed in the field. Picking and packing grapes, vegetables, and melons in the field may not affect the overall level of employment in preparing these crops for market, but field packing increases “farm” and decreases “nonfarm” employment.

The most important reason that there are as many farm workers in the 1990s as in the 1960s is that so many more fruits and vegetables are produced today. It is sometimes hard to appreciate how the expanded production of labor-intensive crops—reflected in both larger acreages and higher yields—creates additional jobs for farm workers.

Broccoli production provides an example. The average American’s consumption of

fresh vegetables rose 23 percent to 136 pounds per person during the 1980s, but the increase was sharpest for broccoli: the *per capita* consumption of fresh broccoli almost tripled from 1.6 to 4.5 pounds during the decade. Broccoli is hand-harvested, and its production in California required an average fifty-two hours of hired labor per acre in 1990 (Mamer & Wilkie 1990).[2]

Will Americans continue to consume more hand-harvested fruits and vegetables? The U.S. consumption of most farm commodities increases about 1 percent annually due to population growth, but the demand for many FVH commodities increases another 2 or 3 percent annually, or about as much as personal incomes typically go up, because Americans tend to spend about the same percentage more on fresh fruits and vegetables as their incomes rise. For example, if the population increases by 1 percent and personal incomes rise 2 percent, then expenditures on fresh broccoli and strawberries rise by 3 percent.

The Farm Labor Force

Most persons who work on U.S. and California farms for wages are immigrants from Mexico. Farm labor data are notoriously unreliable, and the two major sources of such data paint very different pictures of who farm workers are.

The Current Population Survey [CPS], the source of most data on worker characteristics, reports that most farm workers are non-Hispanic U.S. citizens. The monthly CPS of 60,000 households includes about 1,500 who worked in agriculture during the previous week and, based on CPS-expansion factors, an estimated 2.5 million persons sometime during the year worked on a farm for wages during most years in the 1980s (Oliveira 1989).

These farm workers were 78 percent white, 14 percent Hispanic, and 8 percent black and other races. White workers were the majority or plurality in every

region of the U.S., including the Pacific states of California, Oregon, and Washington, where white farm workers outnumbered Hispanics 54 to 44 percent (Ilg 1995).

The U.S. Department of Labor [DOL] National Agricultural Worker Survey [NAWS], by contrast, finds that hired workers on crop farms are recent immigrants from Mexico. The NAWS found that 70 percent of the crop workers employed on U.S. farms in 1993-1994 were born in Mexico or Central America and that most had been in the U.S. for less than ten years. Many of these immigrant farm workers are so-called Special Agricultural Workers [SAWs]—aliens who were illegally in the U.S. in the mid-1980s and who were legalized under special provisions of the Immigration Reform and Control Act of 1986.

The NAWS emphasizes that most farm workers are "working poor" adults who are trying to support families with their seasonal farm earnings (Griffith & Kissam 1995); more than 60 percent of the Mexican-born farm workers in 1993-1994 were settled in the U.S., and newspaper accounts emphasize that more and more previously-migrant farm workers are settling in the U.S. (Mydans 1995). However, these immigrant farm workers have relatively low farm earnings—typically $4,000 to $5,000 annually—and they lack the English, skills, and contacts needed to obtain nonfarm jobs that would offer them higher earnings (Huffman 1995).

California farm workers are more likely to be Mexican-born, to be employed by farm labor contractors rather than directly by growers, and to live in nonemployer-provided housing than farm workers in other parts of the U.S. The percentage of male and unauthorized farm workers is about the same in California as in the rest of the U.S. As with most hired farm workers interviewed in the NAWS, most California farm workers do not speak English (only 11 percent in 1990-1991) and few finished high school (only 13 percent).

Despite the legalization of 1.1 million farm workers in 1987-1988, there is a significant and growing percentage of unauthorized workers in the farm labor force. The estimated percentage of unauthorized workers who harvested fruits and veg-

etables ranged from 0 percent in Georgia peaches in the early 1990s to 35 percent in Fresno raisins (Commission on Agricultural Workers 1992:74). Most California estimates were that, six years after IRCA, less than 30 percent of the work force was unauthorized and less than 10 percent of the Stockton tomato harvesting workforce was unauthorized.

The percentage of unauthorized workers in the farm workforce seems to be climbing. The apparent percentage of unauthorized workers in the NAWS, doubled between 1989-1990 and 1993-1994, about 12 to 25 percent nationwide, and 27 percent in California. One reason for the rising percentage of unauthorized farm workers is that so-called "new-new" migrants—indigenous peoples from southern Mexico and Central America, such as non-Spanish-speaking Mixtec Indians—have begun to enter the U.S. farm workforce in significant numbers (Zabin & Hughes 1995). There were relatively few such workers in the mid-1980s, so they did not get legalized.

The dominance of foreign-born workers affects the structure and functioning of the farm labor market, e.g., non-English-speaking immigrant workers often require intermediary bilingual FLCs or foremen to help them find housing and other social services; they are usually more willing to accept variation in days worked and piece-rate earnings than U.S.-born workers; and immigrants are more likely to pay without question charges for housing, transportation, and eating arrangements in areas with farm jobs. Such behavior makes immigrants preferable to U.S. citizens in the eyes of many farm employers (U.S. DOL 1994; Commission on Agricultural Workers 1992).

Most immigrant farm workers do not remain farm workers for their working lives. Instead, farm workers frequently do farm work for a few weeks or months or even a season and then return to Mexico or find a nonfarm job in the U.S. Most farmers do not worry about such worker turnover. As they rely on a foreman or crew boss to bring a crew of workers to their farm, they do not know or care if the same workers return year-after-year. Turnover, or the number of individuals hired to keep a crew of twenty at full strength, sometimes reaches 100 percent or more *monthly*.

One reason why worker turnover is so high is that there are few incentives for workers to remain employed by any one employer. Wages are usually uniform for the task being done, and there are few benefits, such as health insurance or vacation pay, that a worker would forfeit by quitting. Seniority usually does not lead to a preferred place in the crew next year; in most cases, personal ties or favors earn a worker a preferred job, not length of service.

Most of the farm work is done by so-called "professional" farm workers—those who begin doing farm work between the ages of eighteen and twenty-five, do the hardest and highest wage hand-harvest work until age thirty to thirty-five, and then switch from so-called heavy harvesting tasks to such easier tasks as irrigating and pruning. It is these "professional" farm workers who predominate in the NAWS data. A combination of few transferable skills and high unemployment in the early 1990s kept more than 95 percent of them who were doing farm work one year in the farm workforce the next year.

The job ladder for professional farm workers involves a trade-off between hours worked and hourly earnings. Young men often aim to earn $100 daily picking grapes, citrus, or melons for piece-rate wages. After ten or more years, many switch to farm tasks that generate lower hourly earnings but provide easier work and, perhaps more hours. A few of these workers are able to earn higher wages if they acquire a skill, such as equipment operation, or become a crew boss who recruits workers.

Few young Americans dream of growing up to be farm workers. In the past, it was often feared that farm worker children would be trapped by the inadequate education they get because of migrancy and be forced into the migrant farm worker stream for lack of skills useful elsewhere. Most of the evidence today indicates that farm worker children may do farm work alongside their parents as teens but, if they go to U.S. schools, they tend to take non-farm jobs by age eighteen or twenty to avoid being trapped as their parents were. The farm workforce is reproduced abroad; most new entrants to the farm workforce are born in rural Mexico.

The Farm Labor Market

How do 900,000 mostly immigrant farm workers find jobs with the 25,000 California employers who hire them? The farm labor market is like other labor markets in the sense that it matches workers and jobs. However, it handles the three essential functions of a labor market in unique ways.

First, farmers rarely recruit or speak directly with prospective employees. One farmer described his hiring policy: "When we need thirty workers, we call up the FLC, and they supply the workers." This means that recruitment is usually done by bilingual foremen or FLCs in the language of the worker.

Second, agriculture has dealt with the problem of training and motivating diverse workers to work either by paying piece-rate wages—e.g., $10 per bin of oranges picked—so that each worker's pay reflects her productivity, or by paying an hourly wage, but in a manner that permits farmers to control the pace of work, e.g., by, having workers follow a conveyor belt that moves slowly through the field.

Third, many farmers have concluded that it is better to work collectively to maximize the supply of farm workers than to try to identify the best workers and retain them individually.

Contractors or such intermediaries as foremen and crew bosses handle the recruitment of most harvest workers in several ways. In some "farm worker towns," especially those along the U.S.-Mexican border, there is a so-called day-haul labor market. Workers begin to congregate in parking lots at 3:00 or 4:00 A.M., contractors arrive with buses and tell the workers the task and the wage, and the workers then board the bus that seems to offer the best job. Some workers board the same bus every day; others switch from bus to bus.

The most common way in which farm workers are recruited is for the crew boss to tell current workers that more workers are needed and the workers then inform their friends and relatives that jobs are available. Such "network recruiting" is very helpful to employers. There is no need to spend money on "help wanted" ads and workers, who often are grateful

for the chance to tell friends and relatives about jobs, tend to bring only "good" workers to join the crew.

Decentralized hiring by contractors and crew bosses means that there are many farm labor markets. These markets may appear to be similar in the sense that many of the jobs involve harvesting, most of the workers are Mexican immigrants, and the piece-rate wages tend to be similar from field to field. Nonetheless, take-home pay can vary significantly from worker to worker.

Once hired, workers must be motivated to work. There are two major wage systems used to pay seasonal farm workers. According to the NAWS, 70 percent of the jobs held by California farm workers in the early 1990s offered hourly wages, and the remaining 30 percent piece-rate wages or a combination of hourly and piece-rate wages (U.S. DOL 1993b:36-7).

According to earnings data collected from employers, the average hourly earnings of farm workers traditionally have been about one-half of nonfarm private sector earnings, both in California and throughout the U.S. However, in the mid-1970s and the mid-1980s, the ratio of farm to nonfarm hourly earnings rose above 50 percent. Beginning with the end of the *bracero* program in the mid-1960s, the ratio of farm to nonfarm earnings in California crept steadily upward, reaching 58 percent of nonfarm levels in 1977. The California farm to nonfarm earnings ratio fell to 51 percent in 1983, rose in 1989 after the minimum wage was increased, and then fell sharply in the early 1990s [see **Figure 3**].

In the rest of the U.S., by contrast, the farm to nonfarm earnings ratio behaved differently, remaining below 50 percent throughout much of the 1970s and rising to 50 percent only in 1989, again in response to the 1988 minimum wage increase to $4.25 that affected most farm workers.

Some employers pay more—$4.50 or even $5—in order to be able to select the best workers, but reports that U.S. farm workers' hourly earnings averaged, for example, $6.54 in 1995 and $6.83 in California, can be misleading because these average earnings data are weighted by the hours that the various subgroups of workers work. For example, average hourly

earnings of workers on a farm with a tractor driver paid $7 hourly for seventy hours of work weekly, and two $4.25 hourly hoers who each work thirty-five hours, would be reported by USDA to be $5.62 ($490 + $297.50 divided by a total 140 hours of work), even though neither the tractor driver nor the hoers is earning this average reported wage.

Piece-rate wages seem to be more straightforward, but there are few consistent time-series data on piece rates that vary by commodity, availability of housing, season, etc. Under piece-rate wages, workers are paid, e.g., $12 per bin of oranges picked, or $0.16 per each 25 pounds of raisin grapes cut and laid on a paper tray to dry, and guaranteed at least $4.25 hourly.

In addition to wages, many farm workers receive unemployment insurance payments when they are without jobs. In California, virtually all employers are required to cover their workers under the UI system, which in 1994 collected $2.8 billion in employer contributions and paid $3.3 billion in UI benefits to unemployed workers.

The third dimension of the farm labor market is retention—what do farm employers do to identify the best workers, and persuade them to return to the farm? The answer is not much.

Perhaps the easiest way to describe prevailing attitudes toward worker retention is by analogy to irrigation. Water is vital to produce crops in California and there are two major ways to supply water to the crops: “flooding” a field with so much water that at least some trickles to each plant or laying pipes under the soil so that only the water needed by each plant is allowed to “drip” to it.

The choice depends largely on the cost and availability of water. Where water is scarce and expensive, farmers tend to invest in drip irrigation systems; where water is cheap, farmers tend to flood their fields. The choice is either to work collectively so that there is plenty of water for all or to invest farm-by-farm and use water as efficiently as possible.

Farmers acknowledge that securing labor presents the same basic choice: working collectively to maximize the number of

workers available or treating labor as scarce and trying to select and retain the fewest workers necessary.

IS THERE A SHORTAGE OF AGRICULTURAL LABOR?

The most recent manifestation of California agriculture's interest in immigration occurred during the debate that preceded the enactment of the Immigration Reform and Control Act of 1986. IRCA imposed sanctions or fines on U.S. employers who knowingly hired unauthorized alien workers and offered legal immigrant status to many illegal aliens who worked in U.S. agriculture.

IRCA's Agricultural Provisions

IRCA included three major agricultural provisions: deferred sanctions enforcement and the requirement that the INS obtain search warrants to check the status of workers in open fields; the SAW legalization program; and the H-2A and Replenishment Agricultural Worker [RAW] foreign worker programs. Each provision had both anticipated and unanticipated consequences.

IRCA made significant changes in agricultural enforcement practices. Before IRCA, immigration enforcement in agriculture usually involved the Border Patrol driving into fields and apprehending aliens who tried to run away. Farmers pointed out that the INS was required to obtain search warrants before inspecting factories for illegal aliens and argued that the INS similarly should be obliged to show evidence that illegal aliens were employed on a farm before raiding it. IRCA extended the requirement that the INS have a search warrant before raiding a workplace for illegal aliens from nonfarm to agricultural workplaces.

IRCA created two legalization programs: a general (I-687) program that granted legal status to illegal aliens if they had continuously resided in the U.S. since 1982, and the Special Agricultural Worker (I-700) program that granted legal status to illegal aliens who did at least ninety

days of farm work in 1985-1986. It was much easier for illegal alien farm workers to satisfy the SAW work requirement than it was for nonfarm aliens to satisfy the I-687 residence requirement. Some 1.3 million SAW applicants came forth, although it is likely that only a portion were legitimate agricultural workers.

All were supposed to be experienced farm workers, and farmers expected a significant movement of now-legal workers to restaurants, hotels, and other employers who could offer year-round and less strenuous work. Employer sanctions, if successful, could have further depleted a source of argicultural labor.[3]

Part of the last-minute farm worker compromise that allowed IRCA to become law were a Replenishment Agricultural Worker program and changes to the non-immigrant H-2A program that permits farmers with vacant jobs to bring foreigners to fill them if U.S. workers are not available. Both the RAW and the H-2A program permit the admission of legal foreign workers.

RAW program admissions depended on national calculations of farm labor "need" and supply made by the Secretaries of Labor and Agriculture (Martin 1990). However, continuing illegal immigration and the proliferation of "documented illegals" in the farm workforce made it unnecessary to admit RAWs during its four-year life from 1989-1993. At no point could an IRCA-related shortage of agricultural labor be detected.

[3] No one knew how many illegal aliens were employed in U.S. agriculture in the mid-1980s. Most farmers and farm worker advocates accepted a USDA estimate that 350,000 illegal aliens were employed in U.S. agriculture sometime during a typical year, and this number became the anticipated maximum number of applicants.
However, the major surprise was that 1.3 million aliens applied for SAW status, a discrepancy mostly attributable to the ease of fraudulent application, not to a much larger illegal labor force than anticipated. California Unemployment Insurance data, for example, suggest there should have been 200,000 legitimate SAWs, but 700,000 applications were submitted (Martin 1990). Employers argued that independent estimates of SAWs in agricultural employment, which were likewise only one-third the number of applicants, implied that two-thirds of their labor supply had left for better union jobs. Some SAWs did leave agriculture, but the major reason that so few SAWs were "still working" there is that many who legalized had not been farm workers at all.

Instead of national calculations triggering RAW admissions, U.S. farm employers facing shortages could individually initiate requests for H-2A workers. This indicator of local labor shortages did not jump to requests for 200,000 alien farm workers per year as expected; instead H-2A admissions dropped from 30,000 in 1989 to about 15,000 in FY 1995. Most of the reasons the H-2A program did not expand lie in continuing illegal immigration and false documents. Shrinkage of the H-2A program, on the other hand, is partly due to mechani-zation of the Florida sugarcane harvest.

November 1995 Employer Survey

In November 1995, California's Employment Development Department mailed a two-page survey to a 5 percent sample of reporting units with SIC codes 01 (crop production), 02 (livestock production), or farm-oriented 07 (agricultural services).[4] Some 1,000 surveys were mailed and 197 were returned for a 20 percent response rate.

Agricultural employers were asked about their employment of seasonal workers—persons employed for less than 150 days in 1995. About 55 percent of the responding farms—102 farms—employed 5,100 seasonal workers in 1995, or an average 50 seasonal employees per reporting unit.

The purpose of the survey was to determine if INS's Operation Gatekeeper or other border control efforts affected the supply of seasonal workers in 1995 compared to 1994. For this reason, there were a number of questions asked about the characteristics and availability of seasonal workers.

Virtually all seasonal farm workers hired in 1995 were immigrants who were re-

[4] There were 36,200 reporting units in California in 1994 with SIC codes between 01 and 09, agriculture, forestry, and fisheries. They paid total wages of $6.6 billion and, as most workers are low earners, about 56 percent of the wages paid were taxable for UI purposes (California employers pay a tax on the first $7,000 paid to workers to cover the cost of UI benefits). Agricultural employers made $167 million in contributions in 1995, and unemployed workers received about twice as much in UI benefits—$335 million.

cruited by fellow workers (36 percent), foremen (31 percent), or labor contractors (11 percent)—the "other category" included 22 percent of respondents, and they relied mostly on seasonal workers returning to their farms—about two-thirds of the seasonal workers employed in 1995 were reported by employers to have worked on their farms in 1994. None of the responding employers used the Employment Service or a union hiring hall; just one used the H-2A program to obtain two workers.

Responding farms provided estimates of the number of seasonal workers with various types of work authorization documents. According to employers, about 5 percent of the seasonal workers hired in 1995 were U.S. citizens, 46 percent were legal immigrants, and 9 percent were believed to be falsely documented. Farmers reported that they did not know the legal status of 41 percent of their seasonal workers.

Farmers were asked to estimate how many workers were employed in California agriculture for the first time in 1995, and they reported that about 1 percent were first time U.S. workers.[5]

According to farm employers, about 46 percent of the seasonal workers hired in 1995 presented greencards (INS I-551 forms) to establish their right to work in the U.S., while 45 percent presented social security cards. About 7 percent presented SAW documents, which are no longer valid. To prove their identity, 72 percent of the workers presented drivers' licenses.

The seasonal workers hired in 1995 have characteristics similar to those reported in the NAWS. For example, 68 percent were male, 87 percent were born in Mexico, and 69 percent were under age 40. The most common hourly wage paid to seasonal workers in 1995 was $5.38 per hour, and 45 percent of farm employers reported that this was a higher wage than was paid in 1994.

[5] Surveys done for Employment Services in the mountain states in summer 1995 found higher turnover—in some crops, as few as 15 percent of the seasonal workers were employed the year before (Thilmany 1995).

Few farm employers house seasonal workers on their farms—only 26 percent reported that they provided housing for seasonal workers, but 61 percent reported that their seasonal workers lived "in town." One farmer used the H-2A program to obtain two foreign workers in 1995, and four others investigated the H-2A program, but ninety-two did not. Among those who commented on the H-2A program, most did not know about the program, and those who did know about it asserted that it was too expensive or bureaucratic to use to get farm workers.

About 35 percent of the responding farms used a farm labor contractor or custom harvester to obtain seasonal workers in 1995 and they got an average sixty-seven workers from such intermediaries. Contractor employees received an average $5.59 per hour, slightly more than workers hired directly, and an average overhead rate of 40 percent was paid to cover the FLC's payroll taxes and costs associated with hiring and providing toilets, etc., for farm workers.

The survey asked how IRCA was affecting farming operations, and most employers asserted that the government needs to develop a better employee verification system and that an agricultural guest worker program is necessary.

Yet, most employers had no trouble finding seasonal workers in 1995—91 percent of employers who hired seasonal workers in 1995 reported that they were able to find enough seasonal workers. The nine employers who reported difficulties finding sufficient seasonal workers cited the general unavailability of workers as well as a unique reason, such as planting additional acreage or bad weather.

County and commodity specific details from the survey emphasize the same points, *viz*, most used informal recruitment methods to obtain seasonal workers, most paid about $5 per hour, and virtually all employers had enough seasonal workers in 1995.

PROPOSED GUESTWORKER PROGRAMS

There are two major types of guestworkers, nonimmigrants and probationary immigrants, and two major methods to admit them to the U.S., through certification or attestation procedures. Nonimmigrants are foreigners in the U.S. for a specific time and purpose, and experience in the U.S. as a lawful nonimmigrant is not supposed to advance a person's priority to enter the U.S. as an immigrant.[6]

Probationary immigrants, on the other hand, if they are still needed and do a sufficient amount of qualifying work, can "earn" an immigrant status. European guestworkers were probationary immigrants, and RAWs would have been.

There are also two major ways to admit guestworkers. Certification means that the border gate stays shut until a government agency agrees with the employer that there is a shortage of U.S. workers, and then the foreign workers are admitted to fill a specific job vacancy under contracts approved by the government.[7] Attestation, on the other hand, means that employers open the border gates with their petitions asserting that they could not find U.S. workers after attempting to recruit them at prevailing wages, and the border gate stays open until complaints and enforcement prompt the government to shut the door.

California farmers developed a propo-sal in February 1995 to substitute an attestation procedure for the current certification procedure. Under the growers' pro-

[6] Thus, H-2 workers employed in 1985-1986 were not eligible to apply for the SAW legalization program, which was restricted to persons who were unauthorized workers on U.S. crop farms.

[7] Under the H-2A program, growers must ask DOL to certify their need for workers at least sixty days before the shortage is anticipated. DOL does not certify that growers need H-2A workers unless the grower tried to recruit U.S. workers at prevailing wages and with offers of free housing, transportation, and contracts for work.

posal, employers would attest that they face labor shortages after attempting to recruit workers at prevailing wages. Associations, farmers, or farm labor contractors would fax applications that include promises to recruit local workers and to pay prevailing wages to the U.S. Department of Labor. DOL could review the request for completeness and accuracy, but not initiate an investigation unless there was a complaint. Unless DOL disapproved the application within seven days, growers would be free to employ foreign workers, either workers in the U.S., or those abroad.

Growers would pay for the administrative cost of the program with a fee equivalent to their payroll tax savings for social security and unemployment insurance taxes—perhaps 12 to 15 percent—that would not be paid on behalf of the foreign farm workers. Foreign farm workers admitted under the program could be shifted from farm to farm and could remain in the U.S. for up to thirty-six months. Up to 30 percent of each worker's wages would be withheld and sent to the U.S. consulate nearest the workers' hometown for pickup, or forfeited by workers who failed to appear to collect the withheld wages.

RECOMMENDATIONS

The certification procedure used to determine whether to admit H-2A workers is rife with controversy and litigation. Farm employers criticize it for being too bureaucratic, costly, and uncertain. Farm worker advocates criticize it for permitting employers to obtain the foreign workers who, they assert, employers prefer because the H-2A workers must please their employers to remain legally employed in the U.S.

The government is not well suited to mediating between these parties. If experience has demonstrated anything, it is that, if the only party that wants to make the H-2A program work is government, the program will not work smoothly.

However, the H-2A program may be a bit like democracy—it's not perfect, but it does look better than the alternatives. To my knowledge, no country admits unskilled foreign workers on the basis of employer attestations of labor shortages. I find it hard to believe that, given the history of controversy surrounding the employment of foreign workers in U.S.

agriculture, the U.S. will in the late 1990s introduce an attestation program for alien farm workers.

All governments make employers who want temporary foreign workers pay for the privilege. However, employers currently pay lobbyists to push for the fewest and lowest hurdles between themselves and the foreign workers they want. This means that employers pay for the privilege of obtaining access to foreign workers up front and then reap the rewards of using foreign workers afterward. This accentuates dependence on foreign workers and means that, once an employer becomes hooked on foreign workers, there is no continuing economic incentive to look seriously at U.S. workers.

If the likely outcome of the debate over certification versus attestation is a change in certification procedures, then I suggest careful consideration of such changes as substituting employer-paid user fees for some of the regulations that now govern admissions.

I suggest that employers who bring H-2A workers into the U.S. pay a user fee equivalent to 15 to 25 percent of the wages paid to H-2A into an industry-specific trust fund. This fund, administered by employers, labor, and government representatives in a manner similar to current trust funds that promote, *inter alia*, milk and pork, should be charged with spending the funds collected in a manner that would end the industry's dependence on nonimmigrant workers.

Trust funds would, I believe, have several advantages over the current system. First, they would encourage employers to return to the U.S. labor market to look for workers—experience shows that, once employers master the intricacies of the H-2A program, they rarely return to hiring U.S. workers. Second, trust funds tie the funds available to find alternatives to foreign workers directly to dependence on foreign workers. If there were 200,000 foreign farm workers, each earning $5,000, then a 25 percent user fee would generate $250 million to administer the program and to find alternatives to foreign workers.

Third, tripartite administration of the program permits the parties closest to the

problem of insufficient U.S. workers—those who have the most expertise in the causes and solutions for labor shortages—to deal with ending dependence on foreign workers. Tripartite administration may reduce the controversy and litigation that usually surrounds the H-2A program.

POLICY ANALYSIS OF FOREIGN STUDENT VISAS

BARRY R. CHISWICK
UNIVERSITY OF ILLINOIS AT CHICAGO

"Foreign students" are foreign nationals who are in the United States on temporary visas for the expressed purpose of attending a U.S. college or university or a related training program. They are a familiar presence on American campuses and they play an integral part in the intellectual life of these campuses, both as students and as scholars, often serving in academic apprenticeship roles. Unlike other foreign nationals in the U.S., such as illegal aliens, refugees, and permanent resident aliens, who have been extensively studied and discussed, there has, unfortunately, been remarkably little research on, or public policy discussion of, foreign students. Foreign students play an important role in one major sector of the economy (the higher education sector) and many enter the broader labor market, some in an illegal status (e.g., violating the work restrictions on their student visas) and others on temporary work visas or as permanent resident aliens. Public policy regarding foreign students needs to be made, not in a vacuum, but with an understanding and weighing of both the positive and negative aspects of their presence. The positive aspects need to be encouraged, while the negative aspects need to be curtailed.

The United States as a Magnet

The United States is a magnet for foreign nationals seeking university level and advanced (graduate) level training. This is particularly true in the fields of science (biological and nonbiological), engineering, computer science, mathematics,

certain social sciences (e.g., economics) and, more recently, business and management. Hereafter these fields are referred to collectively as "science."

Tables 1 and 2 present data on the admission of foreign students into the United States over time and by country of origin. Although there have been ebbs and flows, there is little trend in the number of foreign students admitted annually—241,000 in 1981 and 257, 000 in 1993 (including 4,383 in the vocational training program). With the growth in college and university enrollment over this period (from 12.4 million to 14.4 million students) there also has been little change in the number of admissions of foreign students per hundred students enrolled in U.S. colleges and universities, a small decline from 1.9 per hundred in 1981 to 1.8 per hundred in 1993. By country of origin [**Table 2]**, foreign student admissions now come primarily from Asia (61 percent), with Japan (16 percent), China, Taiwan and Hong Kong (14 percent), Korea (9 percent), and India (5 percent) the primary sources. Other important source countries outside of Asia are Canada, Mexico, the United Kingdom, Germany, and Spain.

There has, however, been an increase in the stock of the foreign student population in the United States, from about 300,000 in 1981 to just more than 450,000 in 1995.[1] Relative to the total enrollment in colleges and universities, foreign students have increased from 2.5 percent of the student population to just more than 3 percent.

The growth in the foreign student population relative to annual admissions reflects a lengthening in the average stay in student visa status. This has been due, in part, to the increase in the proportion of foreign students in graduate-level education, which generally involves a longer stay in a U.S. educational insti-tution than does enrollment, often for just one semester or one year, in an undergraduate program.

Foreign students now comprise about 1 percent of enrollment in associate degree (two-year college) programs, 2.5 percent

[1] The data in this paragraph and the next two paragraphs are from the Institute of International Education (1995).

in bachelor's (four-year college) programs, and just more than 9 percent in graduate level programs. Or, expressed as a proportion of foreign students, 13 percent are in associate degree programs, 41 percent in bachelor's programs, and nearly one-half (46 percent) are in graduate level programs. By field of study, nearly 30 percent are in the physical and life sciences, engineering, mathematics, and computer sciences, 20 percent are in business and management disciplines. In contrast, less than 4 percent are in the humanities.

There are two fundamental reasons, not necessarily mutually exclusive, why foreign nationals seek a student visa: (1) to obtain high quality education in the United States that may not be available at all or in the same form in the home country; (2) the student visa may be the easiest or least costly mechanism for entering and remaining for some time in the United States.

In spite of the many shortfalls and failings in its system of higher education, the United States is recognized inter-nationally for having the highest quality and most flexible college and university system in the world. This is even more so for graduate-level education than for undergraduate education, although it is true at the undergraduate level as well.

The students feeding into this system come from two primary sources—U.S. trained (grades Kindergarten through four years of high school) students and foreign students. The U.S.-trained students often come from middle schools and high schools that are not up to the quality standard expected at the university level. In particular, while U.S. schools emphasize original thinking rather than rote learning, compared with some schools in some other countries they are not as demanding of their students in terms of classroom hours and homework, and they do not provide high quality learning in mathematics or science.

Moreover, many foreign students, particularly at the graduate level, are drawn from among the best and the brightest from around the world and often have had outstanding training in secondary schools and institutes in their countries of origin. The foreign students can compete very successfully with U.S.-trained students for college and uni-versity admission, particu-

larly at the graduate level. Indeed, in spite of a preference on the part of colleges and universities for U.S.-trained students, they admit foreign students on the basis of their outstanding records.

It is not by coincidence that foreign students are disproportionately in science-oriented fields rather than uniformly distributed across all fields. The United States has a particular comparative advantage in training in the science-based fields in contrast to the humanities; the U.S. is at the forefront of scientific research in many fields. Moreover, science involves inter-nationally transferable skills in contrast to the tendency for the humanities to be much more country specific. Medicine, for example, involves the human body and, although environmental factors may differ, the human body and the biological processes it involves are not country specific. In contrast, the legal system and the institutional environment in which the legal system operates is very much country specific. As a result, a "disproportionate" number of high- quality foreign students apply for U.S. science, rather than humanities, pro-grams. The result is a larger proportion of foreign students in science and a larger proportion of native-born students, who have more of the U.S.-specific skills, in the humanities. These differing relative proportions do not imply discrimination nor do they imply an "imbalance" that needs to be corrected. Rather they imply a rational allocation by students across disciplines based on their relative skills.

Another reason the U.S. draws such a large number of international science students is that the language of instruction (English) has become the international language, or the *lingua franca*, of science. Although lesser fluency in English is generally required in U.S. science programs than in U.S. humanities programs, the experience of studying in a U.S. science program improves English speaking, reading, and writing skills that now are required of scientists who wish to operate on an international level, if only by reading international journals. Indeed, even science journals published in non-English speaking countries increasingly are published in English.

There are, however, less laudable reasons for foreign nationals to seek a foreign student visa. A foreign student visa can be the easiest long-term visa that many for-

eign nationals can obtain. It has a longer duration than a tourist visa, puts one at less risk and provides greater freedom of movement than being in an illegal status, and does not require demonstrating a "well-founded fear of persecution" if one returns to one's home country (refugee visa). Moreover, a foreign student visa does not involve having one's name placed on a waiting list or backlog, as is often required for a permanent resident alien visa. Indeed, most potential immigrants cannot claim refugee status, do not have close relatives in the United States, and either cannot qualify for or, especially if living outside the U.S., cannot find an employer willing to petition for the labor certification that is needed for an occupational preference visa. As a result, most potential immi-grants have little prospect for obtaining an immigrant visa.

At least some applicants for a foreign student visa are motivated by the desire to obtain a "cheap" visa to enter the U.S. rather than by a genuine interest in studying in a U.S. institution and then returning to their country of origin. While in the United States they may "search" for ways of obtaining a resident alien visa, such as marrying a U.S. citizen or finding an employer who will petition on their behalf for a labor certification. Both mechanisms for obtaining a visa are easier if one is inside the U.S. in a legal status than if one is in an illegal status or outside the United States.

Advantages to the United States

The foregoing outlined reasons why foreign nationals have a "demand" for foreign student visas. The crucial question is: Why does the United States "supply" or make student visas available?

Foreign students, especially graduate students in science, are important in fulfilling the two key roles of a university, the transmission and generation of knowledge. With a relative "shortage" of native-born students seeking advanced study in science there is a relative shortage in these fields of teaching assistants [TAs], research assistants [RAs], and postdoctoral fellows. Yet, the current economic situation in higher education in the United States has made graduate students essen-

tial in the functioning of most colleges and universities, particu-larly the large research universities.

The economics of teaching under-graduates requires a large number of teaching assistants, graduate students who grade homework and examinations, tutor students, lead discussion sessions, supervise laboratory experiments, and teach small independent sections of basic courses. Without the graduate student teaching assistant services the cost of higher education would increase significantly.

Moreover, there is much validity to the often-made argument that part of the training of graduate students involves their learning how to teach and that the best way to do that is through supervised hands-on experience or on-the-job training. Supervised teaching experience sharpens an individual's own basic skills in science and provides the necessary training for the teaching many graduate students will be doing upon completion of their advanced degree program.

Similarly, science-based research projects at the major universities depend on research assistants and postdoctoral fellows, many of whom are foreign nationals. This research, generally funded by the federal government and private foundations, now often requires the input of research teams, and an important component of these teams are the RAs and postdoctoral fellows. A de-cline in foreign graduate students would raise the cost of research to the funding agencies and decrease the amount of research funded and performed. Yet, this university-based research is vital to maintaining the frontline position of the United States in science and technology.

The comparative advantage of the United States in international trade is in products (goods and services) that are intensive in "human capital." To maintain this comparative advantage requires a labor force well-educated in science and a scientific community that is advancing the frontier of knowledge. Foreign students, whether in teaching or in research, help maintain the competitive edge of the United States.

There are also potential benefits to the U.S. when the foreign students graduate from their science-based programs of study. If they return to their country of origin or to

a third country, they carry with them links to the United States that can be invaluable in enhancing both trading opportunities and international collaborative research. A negative aspect, however, may be a technological "leak"—with foreign countries learning U.S. technological secrets. One partial pro-tection is security clearances for those working on highly sensitive projects involving national security. But in another sense, it is very difficult for any democratic country to maintain non-classified technological secrets developed in universities, regardless of whether or not there are foreign students. These ideas get disseminated rapidly in international conferences, working papers, technical journals, and, most recently, electronic publications.

Among the foreign students in science who remain in the United States, most eventually enter a career that makes at least some use of their training. Their training in the U.S. as graduate students serves as an apprenticeship program in U.S.-specific, as well as international, skills. They develop credentials that are easier for U.S. employers to interpret than the purely foreign credentials of job applicants from outside the U.S.

There is no question that the U.S. economy has been kept at the leading edge of science and technology over the past century in part through the influx of foreign-born scientists. Yet, one objection to occupational-based visas and to foreign student visas is that foreign nationals are "crowding out" U.S.-born scientists by depressing their wage and employment opportunities. It should be noted, however, that for about the past fifteen years there has been a widening of skill differentials in the U.S. and in the other Organization for Economic Cooperation and Development [OECD] countries, that is, the earnings of highly-skilled workers (including those in science-based professions) have increased relative to lesser-skilled workers.

Several reasons have been offered for this phenomenon. One is the internationalization (globalization) of the world economy that has put lower-skilled U.S. manufacturing workers in more direct competition with lower-income workers in emerging third world economies. Another is the rapid pace of technological advance due to the computer revolution that has given more highly-skilled workers an advantage in the labor market, per-

haps because they have adapted more readily to the new technological changes (which would have only a short-term effect on relative wages) or because the new technology is "biased" in favor of highly-skilled and professional workers (which would have long-term effects).

The widening of skill differentials in earnings in the U.S. has been responsible for an increase in income inequality and a higher rate of return to science-based training. The increase in income in-equality has negative social conse-quences. The higher rate of return to science-based occupations has not attracted enough native-born Americans to college and university training to either fill the available slots or to prevent the widening of skill differentials.

Policy Considerations

Thus, in general, foreign students are not "crowding out" U.S. nationals either in colleges and universities or in the labor market. Fewer foreign-origin scientists would undoubtedly increase the earnings of U.S. scientists, but the price to the American economy would be a slower rate of technological advance and further widening in income inequality. There may be particular subsectors that, at particular times, appear to experience a larger adverse impact from foreign students than others. It is difficult, how-ever, to identify these subsectors in advance and even more difficult to develop ameliorative policies; and, because of rapid responses in enrollments and the labor market to economic incen-tives, most such policies would come into play only after market forces already have mitigated the impacts.

There are, however, potential abuses in the foreign student visa program that can be mitigated through some changes in policy.

It is important to enforce rigorously requirements that students be in good standing with the university. Students on academic probation should not be considered to be in good standing for the purpose of a foreign student visa. For students enrolled in courses or at the thesis or dissertation (independent research) stage a document should be required, signed by the relevant person in the student's department (e.g., advisor or department chair), certifying that satisfactory progress

is being made toward completing the degree require-ments or research project.

A condition of entry for a foreign student should be a prepaid return airline ticket from the airport nearest to the university to the country of origin. This ticket should be nonrefundable unless the INS certifies that the student has left the United States, become a permanent resi-dent alien, or is deceased. This is impor-tant to prevent the lack of a return airline ticket from discouraging a return to the home country and encouraging remain-ing in the U.S. in an illegal status.

To reduce even further abuse of a student visa as an instrument for providing legal cover while seeking another visa, two changes in immigration law would be beneficial. The current labor certification requirements for the labor market (occupational) preference visas give a substantial advantage to aliens already living in the United States compared to potential applicants living abroad. A skill-based points system, along the lines used in Canada and Australia, would be an excellent substitute. Even if the skill-based point system included a small number of points for "prearranged employment" in the U.S., it would provide less of an incentive than cur-rently exists to abuse the foreign student visa program.

Under current law there is a three-year waiting period to demonstrate that a marriage to a U.S. citizen is *bona fide* before it qualifies an alien for a permanent resident alien visa. It would be desirable to raise this to a five-year waiting period to reduce even further the incentive to use a foreign student visa as a mechanism for being in the U.S. while searching for a U.S. citizen spouse.

Another deterrent would be a permanent bar to obtaining a resident alien visa or a temporary visa for those found to have violated a significant provision of their foreign student visa, including by being employed in violation of the visa or by submitting a visa application based on a fraudulent marriage.

Regulations currently require that a foreign student visa applicant be able to demonstrate a level of financial support from legally-authorized sources sufficient to cover tuition, fees, room, board, and

other living expenses. This support level can serve as a policy instrument to increase or decrease the number of foreign students by lowering or raising the required minimum level of financial support or by extending its duration beyond the first year in a foreign student visa status.

There are some things that should *not* be done. It has been suggested by some that a quota be set on the number of foreign student visas. Establishing this quota would be difficult: How would the number be determined? How would the limited number of visas be allocated by country of origin, academic discipline, and university? A rationing mechanism would be needed. The visa backlog, now a prominent feature of the resident alien visa system, would make no sense for a student visa program. It would be unreasonable to ask a graduate student or a university to wait, say five years, before the visa could be approved. Administrative procedures could be used to develop a rationing allocation formula or visas could be auctioned off to universities, although either would be likely to be even more hotly contested than the mechanism for rationing immigration visas.

A more fundamental question, however, is why one would want to place a limit on *bona fide* foreign student visas. With the adoption of the administrative procedures discussed above, abuse and fraud in the foreign student visa program would be reduced. It is not obvious that having done so there would be "too many" foreign students in the United States. These visas have served the national interests of the United States and could be expected to continue doing so in the future.

DENIAL OF DOCTORAL OPPORTUNITIES FOR AFRICAN AMERICANS

FRANK L. MORRIS, SR.
MORGAN STATE UNIVERSITY[1]

As the U.S. moves to a *de facto* low-wage industrial policy characterized by high immigration, a low-wage-influenced regional free trade agreement, and a societal value on graduate, more than precollegiate, education, American education's current practices will insure that the majority of African Americans are relegated to second-class citizenship in the next, as in the past, century. The extreme underrepresentation of African Americans (and other minorities) among those who receive doctorates from U.S. universities will be a major factor in a reduced living standard and quality of life for African Americans.

The disproportionate use of federal research funding to provide better access to higher education to non-American citizens over American minorities, especially in the sciences, is a tragic and counterproductive example of actions against our collective American interest.

African Americans have paid, and continue to pay, dearly in human costs because most Americans are *not* aware that in the new world order skilled people, not low wages, are the only sustainable comparative economic advantage. American public investments, especially race- and class-equitable investments in human capital and education, often are discredited and receive low public policy priority. Lester Thurow, Dean of MIT's Sloan Business School puts it best, noting that if economic success was determined by who

[1] At the time this paper was presented to the Commission, Frank Morris was at Morgan State University. He has since retired.

was able to invent the best new products, then it would make sense to concentrate our educational resources on the top 25 percent of our labor force—as the U.S. currently does. If, however, the key to economic success is being the cheapest and best producer of products, then the education of the bottom half of the labor force is more critical to effective and efficient production because, if they cannot learn new, high-technology, highly-productive processes, those processes cannot be employed (Thurow 1992:227).

Thurow points out that in a low-wage industrial policy, the societal education resource priority is on the upper 25 percent of the educational distribution. Thus, America has some of the greatest research universities—and many of the worst elementary and secondary schools—in the world. Our private sector and federal government research support to a relatively small number of universities has permitted these selected and elite institutions to become a world-recognized asset. Unfortunately, our world-renowned research universities have not served our African American population well, a situation (almost as bad for other American minorities) that continues because we do not hold our research universities accountable for how well they serve our African American population. In the past, when industrial and manufacturing jobs were more plentiful, this lack of accountability may not have made much difference. Now, and in the immediate future, as our economy becomes more and more dependent upon knowledge-based skills, we no longer can ignore the consequences of gross under-representation in access to the higher-order academic training increasingly vital for economic development.

Even so, Thurow aptly observes that we now know that the past historic explanation for American's economic success was inadequate; historians traditionally overstated the impact of cheap, plentiful, well-located raw materials and farmland in explaining American economic success. America did not become rich because a small population lived in a rich resource environment or because Americans worked harder or saved more than their neighbors. The real reason was that America's resource advantages were combined with the first compulsory public K-12 and mass higher educational systems in the world. Both these advantages, plus some others, gave America its great eco-

nomic edge, especially after World War II. Americans did not work harder, but they worked smarter and they were better skilled. Once rich, it was easier for America to stay rich (Thurow 1992:40).

The benefits most Americans receive come from the differential access of their ancestors, parents—or even themselves—to natural resources that they could exploit without paying either replacement or environmental degradation costs, and from government subsidies, ranging from free or low-cost land, education, help in research, development, and promotion, and, especially, extensive tax subsidies. Our common future heritage depends on effectively utilizing and developing *all* of our human resources—especially our poor and minorities. Current policies and practices in doctoral education are counterproductive to this goal.

The Need for More African American Doctorates

Many current practices place all American graduate students at a disadvantage *vis-a-vis* international students. Many American research universities abuse the concept of merit in responding to the needs of our African American population. There are numerous reasons for comparing African American and international doctoral recipients:

- Non-American doctoral recipients benefit *most* from the *best* graduate financial assistance, while African American doctoral recipients benefit *least*;
- This best university support—in the form of research assistantships—is financed primarily through federal research grants funded from taxes taken from all Americans—including American minorities;
- Research universities have less incentive either to care about or to help produce more American minority scholars if they can find all the students they need—and more—overseas;
- The lack of public accountability, financial incentives, or penalties does not create adequate motiva-

tion for American research universities to produce more American minority Ph.D.s.

Only in America is it necessary to make the argument that it is in our national interest to develop our underutilized human resources (who disproportionately happen to be American minorities). It is already clear that future quality of life, as well as economic development, requires greater utilization of knowledge-based communication and information skills. American Ph.D.s are more likely to stimulate our economy, more likely to pay taxes, and more likely to be creditable role models for future faculty and students. The converse is also true. If current American research university patterns of benign neglect of African American doctoral students in the sciences is allowed to continue, we are mortgaging our future.

The Problem

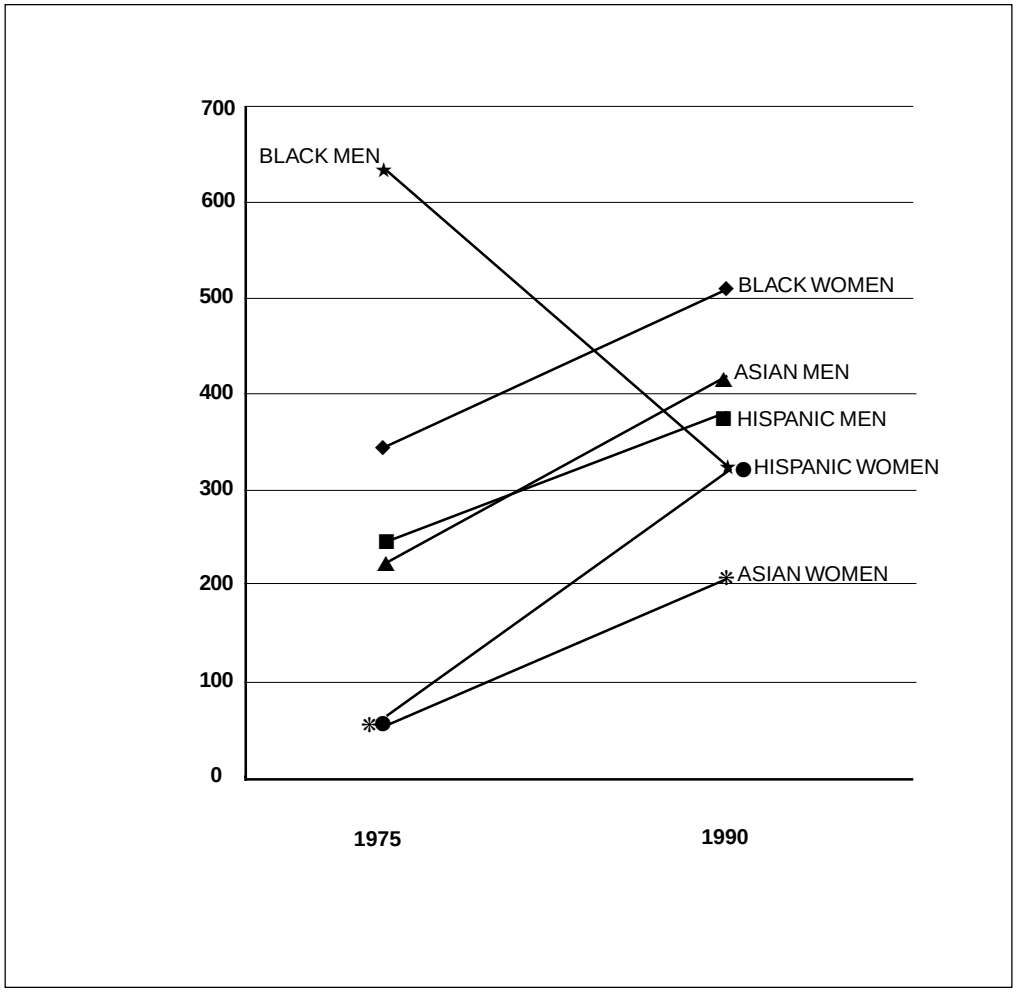
African American citizens constituted more than 13 percent of the U.S. population but received less than 3 percent of the doctorates from U.S. universities in 1990; non-American citizens received 28 percent of all doctorates from U.S. universities that year (Thurgood & Weinman 1991:10,84).

Although African American doctorates have increased from 1975 to 1991, the total is still 16 percent less than the peak year of 1977. This loss is in spite of a 27 percent increase in Ph.D.s to African American women since 1977. African American males are the only underrepresented American minority group that suffered a loss of more than 44 percent in the receipt of Ph.D.s from American universities since 1975-1977 (NRC 1992:64). The number of Ph.D.s going to all other underrepresented American minority groups increased considerably [**figure 1**]; the number of Ph.D.s from American universities going to non-American citizens increased more than 70 percent during that time.[2]

African American males constitute 6 percent of the U.S. population, 47 percent of the U.S. prison population (Hacker

[2] There were 684 African American male doctorates in 1977 and 385 in 1991 (NRC 1992:71). There were at least 9,398 non-American citizen doctorates in 1990 compared to approximately 5,338 in 1975 (Thurgood & Weinman 1991:84)

Figure 1.
Doctorates Awarded by U.S. Universities to U.S. Citizens



Source: Thurgood & Weinman 1991.

1992:197), 5 percent of the private sector top corporate positions, but less than 3 percent of those with access to postsecondary education and less than 1 percent of those who received doctorates from American universities in 1990. In comparison, non-American citizen males received 21 percent of all doctorates from American universities in that same year.[3]

The 1990 Doctoral Project of the National Research Council [NRC] of the National Academy of Sciences documented that American research universities provided better support to the international students who received doctorates compared to African Americans who received doctorates. This greater support for non-American citizens over African Americans held for every doctoral and professional field, including the humanities, education, and the social sciences. (Thurgood & Weinman 1991:24,47).

The result was that in 1990, of the more numerous 9,500 international students, 70 percent received doctorates without incurring any debt. In contrast, almost 70 percent of the much smaller number of African Americans (820) and Hispanic doctoral recipients incurred debt. For 25 percent of the African American recipients and 33 percent of the Hispanic recipients doctoral education debt was more than $10,000 (Thurgood & Wein-man 1991:26,34). The 1991 data is even more discouraging. The greater the amount of debt that doctoral students owe, the greater the gap between America minority students and international non-citizen recipients of doctorates from U.S. universities (NRC 1992: Table 17).

Direct federal grant funding for doctoral support has declined in favor of more loan funding (for American citizens) with the result that almost 70 percent of all funding for graduate doctoral education is in the form of federally-subsidized research assistantships that research university faculty are much more likely to give to international students than to American minorities.[4]

[3] The 6 percent black male population figure is a conservative estimate without the benefit of adjustments to reflect a significant black male U.S. census undercount (Thurgood & Weinman 1991:10,84-85).

[4] In the tables in the NRC study, "university" funding is primarily federally-sponsored research dispensed as research assistantships (NRC 1992).

American universities produced non-American citizen doctorates in fields where they did not produce a single African American doctorate in 1990—in some cases, for more than this one year. Over the last decade this trend is even more devastating. The list in the **APPENDIX** shows the future critical scientific fields where American universities averaged less than one and, in some cases, less than two African American Ph.D.s per year for the entire decade. Remember, 13 percent more Ph.D.s were awarded to international students in 1991 than in 1990.

Doctoral Financing: Racial Bias Without Accountability

In its excellent annual report on minorities in higher education, the American Council on Education (1993) reported that even though more African Americans have been attending college in recent years, the number of African American faculty members has remained stagnant for a decade. In 1980, African Americans represented 4.3 percent of college professors; in 1990 they accounted for 4.5 percent of college professors, only a marginal improvement, and more than half of these teach at historically black colleges and universities.

American universities contend that they cannot find African American faculty because of an alleged "pipeline" problem. Yet, only 55.8 percent of the African Americans who received doctorates from American universities in 1990 were hired by American universities, compared with 68 percent in 1975. The percentage of the much larger number of international doctorate recipients hired by American universities increased from 52 percent in 1975 to 56 percent in 1990. Thus American universities hired a slightly higher percentage of a much larger number of non-American citizen doctoral recipients from American universities than African American doctoral recipients (Thurgood & Weinman 1991:22,50).

Statistics clearly demonstrate that doctorate degrees for African American males declined more than half once the federal government began to cut back on direct assistance. As African American doctoral students had to depend upon American universities as the prime source for financ-

ing their studies, they became much worse off because Ameri-can universities allocated more of their resources to fields where they admit and support foreign students. *Ironically, as much of this university-administered support for international students is in the form of research assistantships, universities use federal funds directly or indirectly to disproportionately fund international, rather than American minority, students.*

If there were no readily available pool of foreign students, American universities would have greater incentives to help develop and increase the supply of American students—possibly even American minority students—in many science fields. Instead, American universities and the major organizations that primarily speak for American education, unanimously supported changes in the immigration law of 1990 that accelerates the recruitment of international scientists and scholars, thus insuring that American minorities continue to be shut out of these academic openings. These are serious charges; let us examine some of the evidence.

Although American university departments do not attribute the dearth of African American doctoral students to the lack of financial aid, data suggests otherwise. In his excellent study commissioned by the Graduate Record Examination Board, Michael Nettles concludes that the reduction in [federal] financial assistance since the 1960s has had a negative effect on prospective African American graduate students at both the master and doctoral levels. That reduction also may explain why more than 60 percent of African American and Hispanic graduate students attend graduate school part-time. In 1970, twice the number of students received fellowships, scholarships, and traineeships as in 1981; the federal budget for these forms of assistance declined by more than 50 percent from 1970 to 1981. While these federal grants decreased, federal loans increased from $717 million in 1976 to nearly $3.5 billion in 1984 (Nettles 1987:1.5). Nettles notes that as federal direct student funding declines, students became more dependent upon universities for assistance, a shift, he asserts, that profoundly affects the ability of African American students to afford graduate school. As universities became the prime determining financing factor for doctoral degrees, African American males fared far worse than any other—especially international—students.

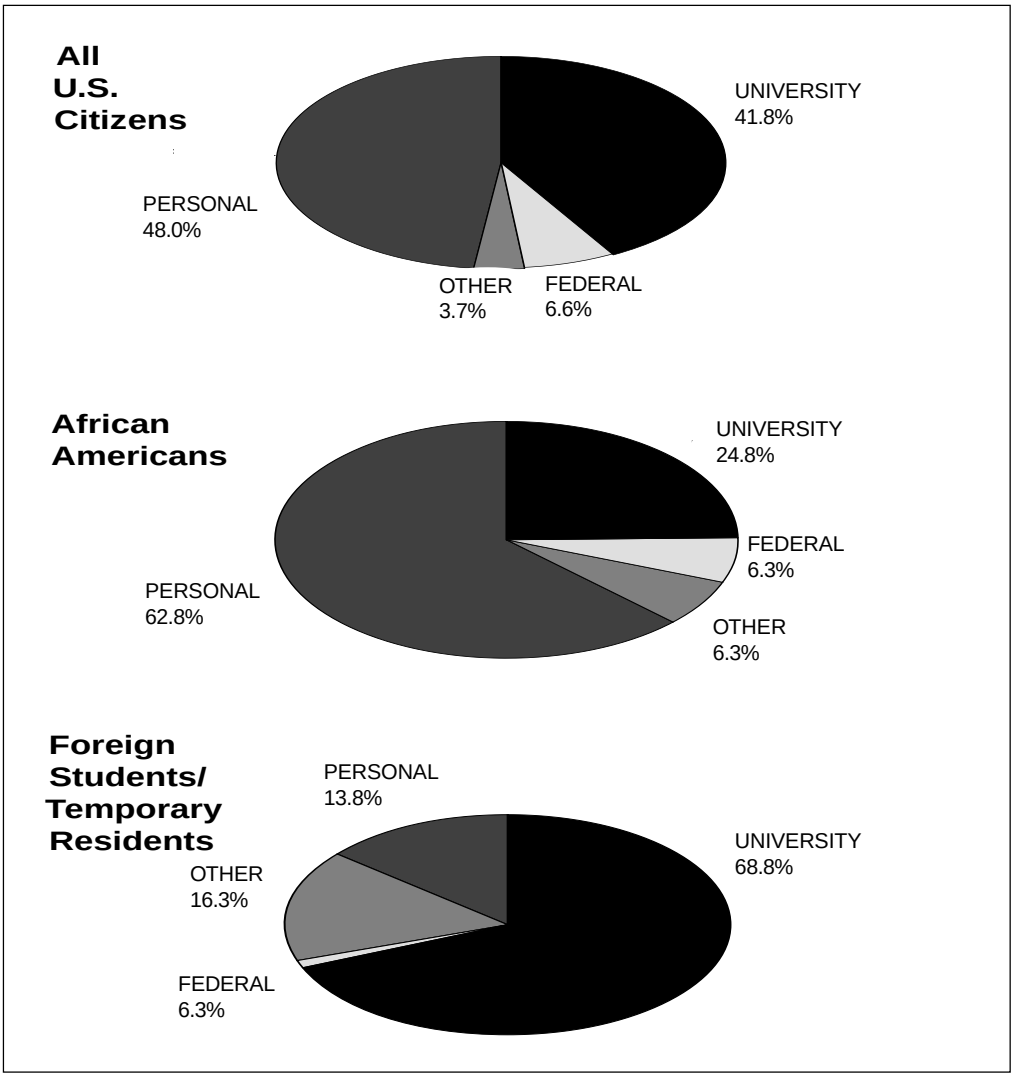
The annual National Research Council 1990 data that traces the fiancing of those who were successful in achieving the doctorates is informative. For international students, American universities were the primary source of doctoral support for 68.8 percent, while for African Americans, universities were the primary source of support for less than 25 percent (Thurgood & Weinman 1991:24,47). For more than 60 percent of African Americans (and Native Americans) the primary source of support for their doctoral education was their own personal funds, such as loans; only 13.8 percent of international students primarily depended on personal funds [**figure 2**].

American universities attempt to explain these trends by contending that minorities are in fields where less university and federal support is available. The different fields misnomer is apparent if we compare the fields where a much higher proportion of American minority students than international students are found. Of African Americans who received their degree in education in 1990, 81 percent listed personal resources as the prime source of financing for their doctoral studies; only 12 percent were primarily funded by American universities. In contrast, only 41 percent of international students who received doctorates in education that year listed personal resources as their primary source of funding; more than 28 percent were primarily funded by American universities. Keep in mind that the absolute number of international students is many times greater than African Americans—or all American minorities combined. This large positive funding percentage in favor of international students translates into almost geometric differences in actual dollars.

Thus, if we just look in the doctoral field where about 50 percent of all African Americans achieve their doctorates, the proportion of African Americans who had to finance their doctoral studies personally was twice that of non-American citizens. *Equally important, American universities were more than twice as likely to provide funds to international students in education than to African Americans* (Thurgood & Weinman 1991:24,47).

We find similar patterns in fields such as the social sciences and the humanities. In the social sciences, 48.5 percent of 1990 African American Ph.D.s financed their

Figure 2.
Sources of Support for
1990 Doctoral Recipients



Source: Thurgood & Weinman 1991.

education by personal funds, while only 22.5 percent of international students had to pay for their education with personal funds. American universities were the prime source of financing for 37 percent of African American Ph.D.s but for 56 percent of international student Ph.D.s (Thurgood & Weinman 1991:24,470.

It is difficult to understand why American universities should favor non-American citizens in the humanities, but they do. Only 28 percent of international doctoral students in the humanities primarily used personal funds to finance their doctoral studies, compared to 50 percent of African American doctoral students. Universities were the primary source of support for almost 57 percent of international students in 1990 compared to only 50 percent of African American doctoral students. Remember these figures are for those who successfully completed their doctorates!

While American universities were giving preferential doctoral financing to international doctoral students over American doctoral students in education, African American and Hispanic doctoral awardees in education were accumulating significant graduate debt to go with high undergraduate debt. One-third of all Hispanic doctoral awardees and more than one-quarter of the African American awardees reported debt of more than $10,000 (Thurgood & Weinman 1991: 24,47). These high debts are often in fields where salaries are lower than in the sciences.

Other indicators show the preference or bias of American university graduate departments toward international students over American minorities—especially African Americans and Native Americans. In both real and total time to complete the degree, international students appear to have the advantage over African Americans and Hispanics. In education, for example, the median total time for non-citizen international students was 12.8 years, compared to 19.6 for African Americans and 16.4 for Hispanics. The real time median differentials were 6.1 for international students in education compared to 8.5 years for both African American and Hispanic doctoral degree recipients (Thurgood & Weinman 1991:15,46). Part of this difference could be related to the

university preference for support for international students in the form of research assistantships that also encourage interaction with faculty and promote the possibility of both mentoring and provision of a basis for a dissertation.

Yet, American universities contend that factors other than their differential allocation of financial aid account for the dearth of minorities in graduate programs. This is despite the indication from Nettles and others that the much lower median family income and extreme difference in black and white family wealth in the U.S. require that minority students, especially African Americans, non-Cuban Hispanics, and Native Americans, assume much greater undergraduate debt burdens than White American graduate students. Nettles strongly suggests (1987:4) that this differential debt burden affects minority and majority students differently when they make education and career decisions. It is an entirely rational decision not to go on to a doctoral degree program when you see that the majority of your peers who do are not favored in comparison with international students and that students of your race are forced to take longer to complete their degrees.

American universities' contention that a "pipeline" problem keeps them from finding "qualified" African American graduate students has less merit after an examination of the American university funding preference for international students (see above). The NRC report notes that such "qualified," potentially successful African American graduate students are disproportionately located on the campuses of historically black colleges and universities. Although such colleges and universities enrolled only about 16 percent of all African American students in American higher education, they were the baccalaureate-granting schools for almost 60 percent of the African Americans who received Ph.D.s in 1975 and almost 40 percent who received Ph.D.s in 1990 (Thurgood & Weinman 1991:32). This author proudly taught and worked on one such campus that, according to recent figures, produces more African American Ph.D.s than any other public American university. Yet American universities do not try actively to recruit extensively or to offer support to all of our African

American science graduates who have the capability to succeed in doctoral programs. So much for the alleged pipeline problem.

Keep in mind that in 1990 international students received more than twice as many doctorates from American universities as all American minorities combined, a trend that clearly seems to freeze out American minorities, especially African American males, from future faculty positions. African Americans resentment is even greater when we see American universities recruit international scholars of color and then label them as "minority," rather than the more accurate "international," faculty.

Three countries provided 44 percent of all non-American citizen doctorates in 1990: Korea and the two Chinas (Thurgood & Weinman 1991:11). Why is there this overwhelming preference in American graduate university departments for international students, especially international Asian students in the sciences?

The lobbying of major educational associations/organizations that represent American universities in support of the 1990 immigration law changes to make it much easier for foreign professors and students to get both access to and permanent status in the U.S. clearly worked to the detriment of U.S. minorities. This trend is likely to accelerate as David Simcox, former Executive Director of the Center for Immigration Studies, noted in a paper presented at the Northeast Association of Graduate Schools meeting (1991:3-4):

> There are several factors that will make these trends worse in the future, the greatest of which is the rapid population growth among the young, highly mobile working-age population in the third world. Almost all third- world countries are falling further and further behind in the race to create jobs for the expanding populations. For example, in the next few years Mexico's labor force will grow at the rate of over 1 million persons per year, but Mexico's economy, even with the most optimistic assumptions about a free trade agreement, will create

less than half that number of new jobs per year. The International Labor Organization anticipates that the third-world labor force will grow by fifty million per year with less than half that number able to find jobs. Many of these economies have been overproducing college graduates for many years. Some, such as India, Pakistan, Korea, and the Philippines, seem to be deliberately overtraining some of their surplus skilled workers with the expectation that they will find advanced training, and possibly employment, in countries such as the U.S. Most of this oversupply will be science graduates and students because those disciplines are viewed as more culturally neutral, because American universities are still considered as the best in science and technology, and last, but not least, the transition to permanent residence in the U.S. is easiest for those with science skills.

This is consistent with the historical preference pattern of American research university faculty for international faculty and students over American minorities, especially African American males. This situation will not change unless major funding and funding incentives for American universities change.

Recommendations

African American and other legislators concerned about American long-term interests must take steps to insure that the resources committed to American minority students in doctoral training by American universities are at least equal to the commitment of taxpayer research support subsidies to international students in all fields. Academic administrators, such as college presidents, provosts, and deans, should make academic department discretionary funding conditional until these departments provide all American minorities doctoral opportunities that are at least equal to their commitment to non-American citizens.

Legislation that will guarantee research assistant-type support for all qualified American doctoral students should be

supported. We should not require American students, especially American minority students from families with less wealth and income, to go into debt to finance their education while we subsidize non-citizen guests to the extent that the overwhelming majority of them get their doctorates debt-free.

Whenever American universities use federal (or state) funds for graduate student research support, and whenever that support covers more than one student, then for every international student that American faculty members chose to support with these government monies, they should also support an underrepresented American minority student.

It is clear that major American research universities are not now going to provide research opportunities for American minority students comparable to those they provide international students. These major heavily-federally-subsidized American research universities *never* have provided opportunities for American minorities of color comparable to those provided by the historically Black colleges and universities. The under-funded Black institutions, however, have been given neither the resources nor the state authority to provide comparable comprehensive graduate research opportunities. Now it is time to address this issue by providing major research commitments to historically black colleges and universities that have successfully demonstrated their ability to graduate quality undergraduates, especially in the sciences. It is likely that only these institutions will provide the quality research environment that will develop the minority talent currently being lost to this nation.

There should be an *American incentive computation* in every federal (or state) research contract that supports doctoral students. Universities where the under-represented minority percentage of Ph.D. graduates in the state equals the proportion of underrepresented minorities in their state population should receive a ten-point bonus in every federal or state competitive research contract. Conversely, universities that use federal funds to support more non-American citizens than underrepresented American minorities in research should have ten points deducted from their score. Such a system would finally create the financial incentives nec-

essary for research universities to develop and recruit underrepresented American Ph.D.s in a manner more comparable to the way they willingly recruit underrepresented minorities from all kinds of limited academic backgrounds for revenue-generating athletics.

FOREIGN STUDENTS IN SCIENCE AND ENGINEERING PH.D. PROGRAMS: AN ALIEN INVASION OR BRAIN GAIN?[1]

JAGDISH BHAGWATI

The Preponderance of Foreign Students in Science and Engineering [S&E] Programs: The Phenomenon

Were the Nobel Laureate Paul Samuelson to walk into a graduate economics class at MIT today, he would be struck by a dramatic difference in the composition of students since he first taught the class. In the 1940s, the class was predominantly American; today, however, more than one-third of the students in the class are foreign students.

This phenomenon is not confined either to MIT or to economics.[2] Thus in 1990, more than one-half of the engineering Ph.D.s in the U.S. were awarded to foreign students. The figures are almost as high in mathematics, physics, chemistry, and computer science [see Figure 1 for S&E and the components Science and Engineering and Figure 2 for major sciences].

[1] Thanks are due to Daniel Greenberg, Phillip Griffith, Brendan O'Flaherty, Duncan Foley, and Andre Burgstaller for helpful conversations. The ideas developed in this paper and the statistics to support them owe greatly to Rao's research.

[2] Indeed, several recent studies of academic labor supply (Bowen & Rudenstine 1992; Ehrenberg 1991; Ehrenberg 1992) note the preponderance of foreign students in Ph.D. programs.

But the phenomenon of foreign student dominance in the U.S. is ill-understood and ill-explained. Its public policy implications are, therefore, couched in alarmist terms, turning the phenomenon into a problem that must be contained when it is, as we argue in this paper, a cause for celebration that calls for a policy of tolerance, even encouragement.

Current Explanations and Policy Suggestions

The conventional explanation of the phenomenon seems to proceed as follows:

- The U.S. has a comparative advantage in promoting gradu-ate education. Foreign students, therefore, come to get it.

- The preponderance of foreign students get into technical and scientific programs because they (chiefly Asians) happen to be "good at" mathematics and far less so at "verbal" skills.[3]

- Finally, Derek Bok (1993) argues that the earnings of doctors, lawyers, and top corporate executives have grown substan-tially relative to those of professors, drawing talented Americans to these professions and away from teaching. Presumably, this argument extends to technical and science Ph.D. programs as well.

  The net result then is to increase foreign student—and reduce native enrollment—in S&E Ph.D. programs. The consequences that are expected to ensue from this phenomenon are fearful.

- Since Ph.D.s plough back into teaching, Bowen and Sosa (1989), in a book featured on the front

[3] An element of this "cultural" argument may be detected in the recent Report of the Committee on Graduate Economics Education (Krueger, et al. 1991), which attributes the increasing mathematization of economics partly to the presence of technically-skilled, but verbally-unskilled, Asian students from the Far East, chiefly Japan, South Korea, Taiwan, and China.

Figure 1.
Foreign Ph.D.s as a Percentage of Total

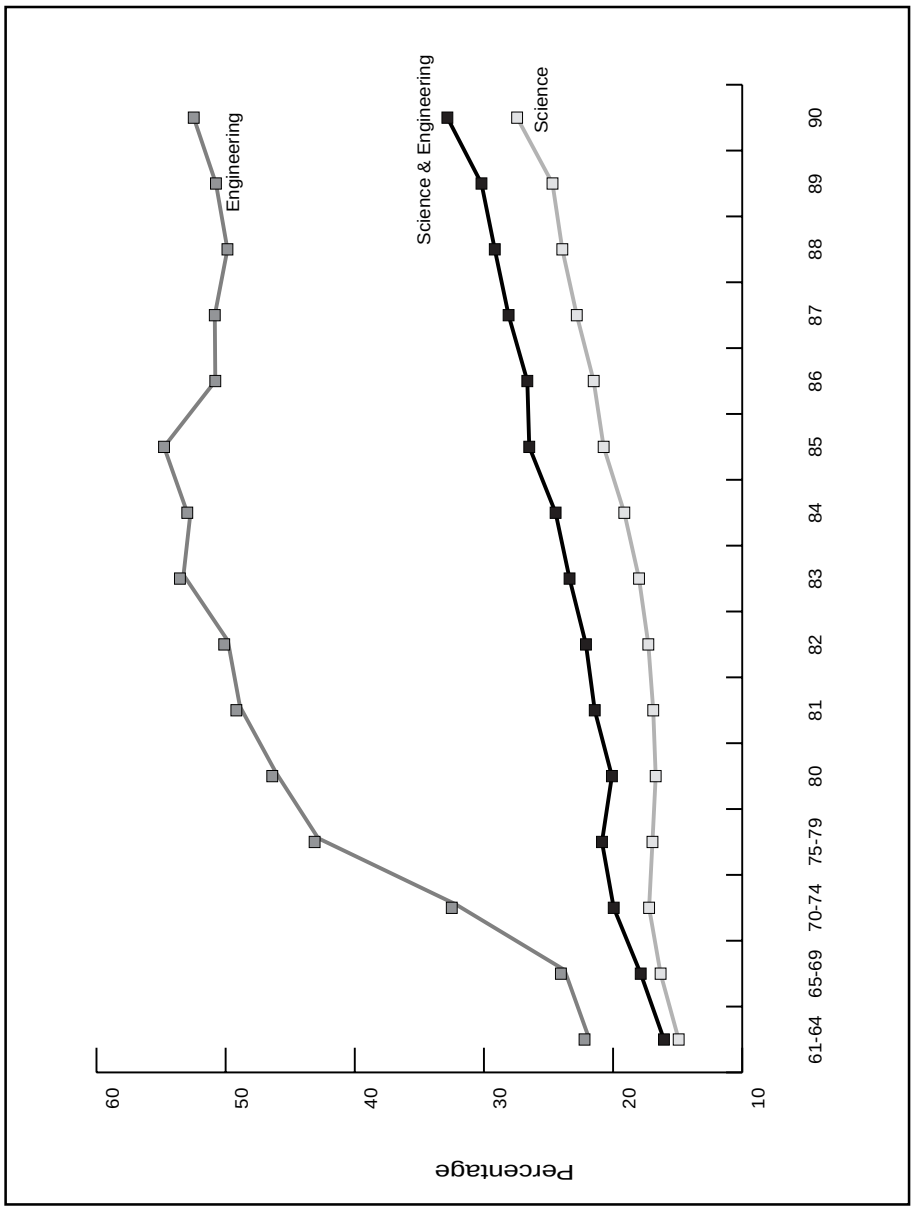

Figure 2.
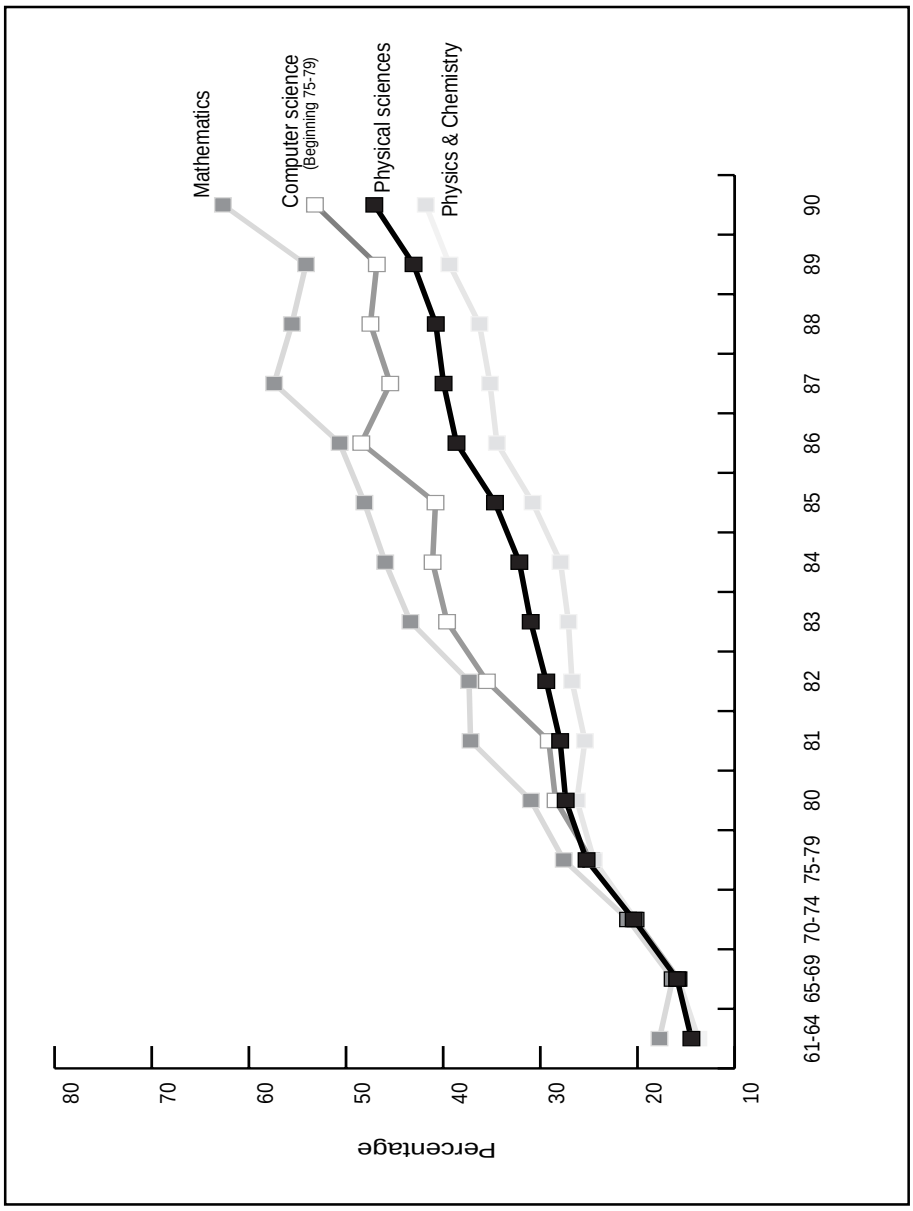
Foreign Ph.D.s as a Percentage of Total



page of the *New York Times*, predict a major shortage of academic faculty in the U.S. by the mid-1990s, due in no small measure to the presence of foreign students who pre-sumably would return to their native lands.

- The preponderance of foreign students in S&E Ph.D. programs also is alleged by many critics to endanger our leadership in research and development.

- Finally, a number of black critics attribute the failure of blacks to get an increasing number of Ph.D.s in S&E programs to the increased dominance of foreign graduate students (e.g., Morris 1993).

The policy prescriptions that naturally follow from these diagnoses center around the notion that "reliance" on foreign graduates is a mistake the U.S. cannot afford. Proposals to restrict the influx of foreign students through visa denial and reduced financial aid have, therfore, been advanced.

OUR RIVAL EXPLANATION

Our view, however, is that the conventional explanation—and the prejudicial implications following from it—are flawed. Our rival explanation of the phenomenon leads, instead, to more sanguine implications and to policy conclusions altogether opposed to currently proposed restrictionist ones.

Alarmist predictions that there would be a shortage of S&E Ph.D.s for the academe (Bowen & Sosa 1989) already have proven false. A recent study by Massy and Goldman of Stanford and RAND, widely reported in the media (Greenberg 1995; Browne 1995), con-cludes that "doctoral production in S&E averages about 25 percent above employment opportunities." Our rival explanation also is better able to suggest why such a large "surplus" could have developed and is likely to persist even though the labor market normally adjusts to correct imbalances because students confidently can be expected to walk away from education that yields low and diminishing returns.

The Theory

At the outset, we must note that the U.S. graduate programs generally admit students on merit. There is no discrimination against foreign students (though in recent years there may have been affirmative action to assist native minorities, which then are marginally favored in relation to *both* foreign and native nonminority students).[4]

This being so, as the applicant pool shifts in favor of foreign students relative to native students, assuming quality to be unchanged, so would the admissions and hence, all else equal, the Ph.D.s awarded.[5]

The explanation of the rising share of foreign students in S&E Ph.D. programs must then be found in the relative shift in favor of foreign students in the application pool. Indeed, it can.

The Explanation

Our explanation proceeds by citing the many factors that have dramatically increased the applicant pool for foreign students.

Immigration economists know that rivulets of immigrants build up into streams as information networking goes to work. Casual empiricism underlines how talented students follow others who ventured into specific graduate programs as pioneers and then spread the word.

In turn, the success of the foreign students from specific institutions abroad serves to supply the necessary "certification" for the admissions committees that new applicants from these institutions are, indeed, likely to be as good as they appear, thus turning them into effective and potentially successful applicants. Thus, new appli-

[4] This complication is of trivial importance, however, as the S&E graduate applicant pool has itself shrunk (Bhagwati & Rao 1996b).

[5] The pooling model explains well why, when the 1965 Immigration Act introduced PTK (Professional, Technical, and Kindred) preferences for which there was *worldwide* competition, and the national quotas generally were not applicable to this competition, the composition of such immigration shifted to such third world countries as India and the Philippines; there were more applicants from these countries in the pool. The model also has been successfully applied econometrically to explain the source-composition of the guestworker (*gastarbeiter*) immigration programs in West Germany (Bhagwati, Schatz & Wong 1984).

cants from Seoul National Uni-versity are treated more seriously in competition than the former ones on whom universitites took a chance and who went on to do well in the programs.

But, for some of the successful "sending" countries, the most significant factor is that they steadily have been building up their technical education to levels comparable to some of our best institutions—often with these institu-tions' help! Entry into these foreign elite schools (such as the prestigious Indian Institutes of Technology [IIT]) often is based on nationally administered entrance examinations with the programs subsidized by the government, permit-ting the most gifted students to attend. A favorable evaluation of the graduates of these institutions when they apply for admission to S&E Ph.D. programs is therefore inevitable; these students often are superbly trained and greatly gifted.

Indeed, all these factors are seen to work in the case of the four Asian countries that provide currently more than one-half of the S&E Ph.D.s: China; India; South Korea; and Taiwan [see **Figure 3** for S&E totals and components and **Figure 4** for major sciences].

Thus, while each of these top "source" countries today has numerous colleges/ universities offering undergraduate S&E programs and degrees, most of the Asian students in American Ph.D. programs are graduates of a very small group of schools that increasingly have come to be regarded as having exceptionally high and improved standards of instruction.

India, for instance, produces about 25,000 engineers (at the bachelor's level) every year; only 2,000 (or about 8 percent) of these graduate from the elite Indian Institutes of Technology. However, 78 percent of recent U.S. engineering Ph.D.s awarded to Indians went to graduates of the IIT. Almost one-half (48 percent) of all Taiwanese students who received Ph.D.s in the U.S. attended either National Taiwan University or Cheng Kung University. Even more telling, 65 percent of the Korean students who received S&E Ph.D.s in the U.S. are graduates of one university—Seoul National University!

Figure 3.
Top Four Asian Countries with American Doctorates

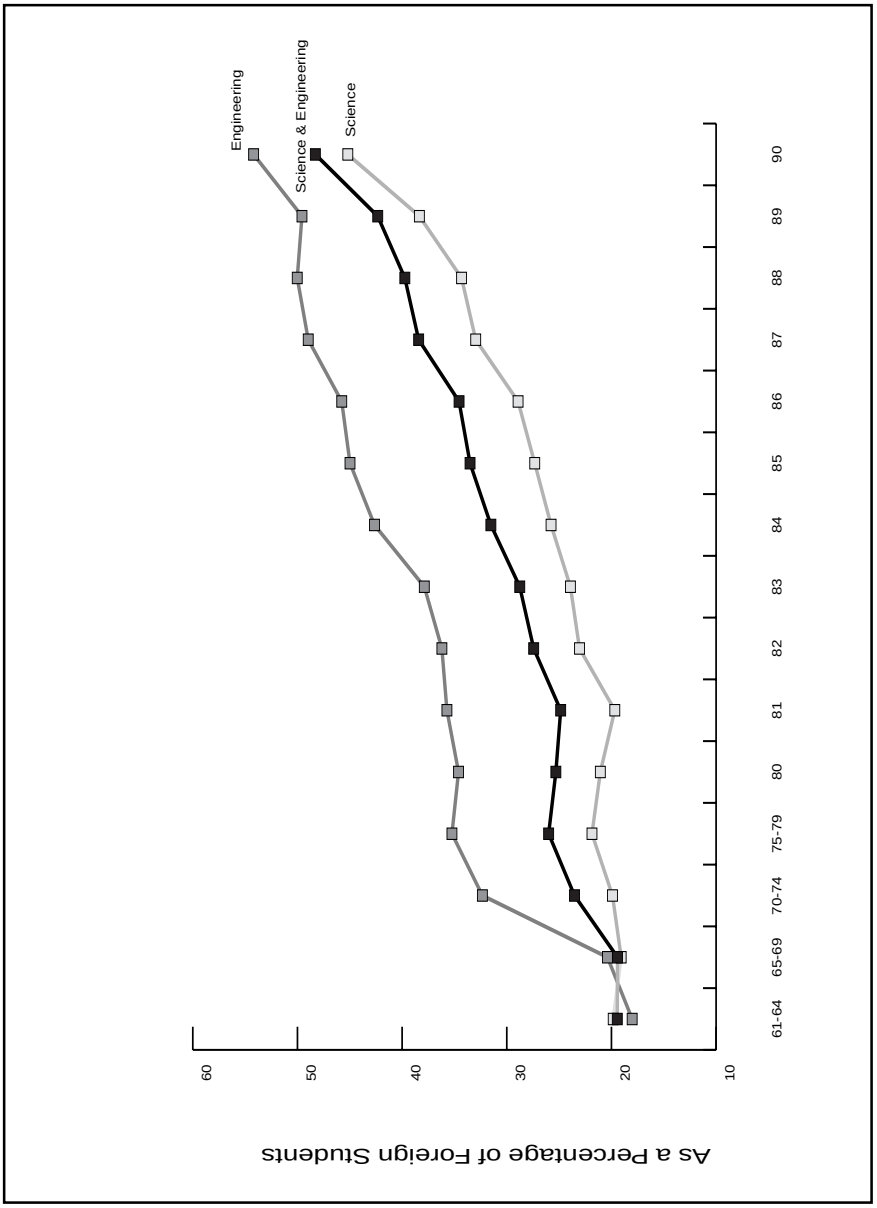


Figure 4.
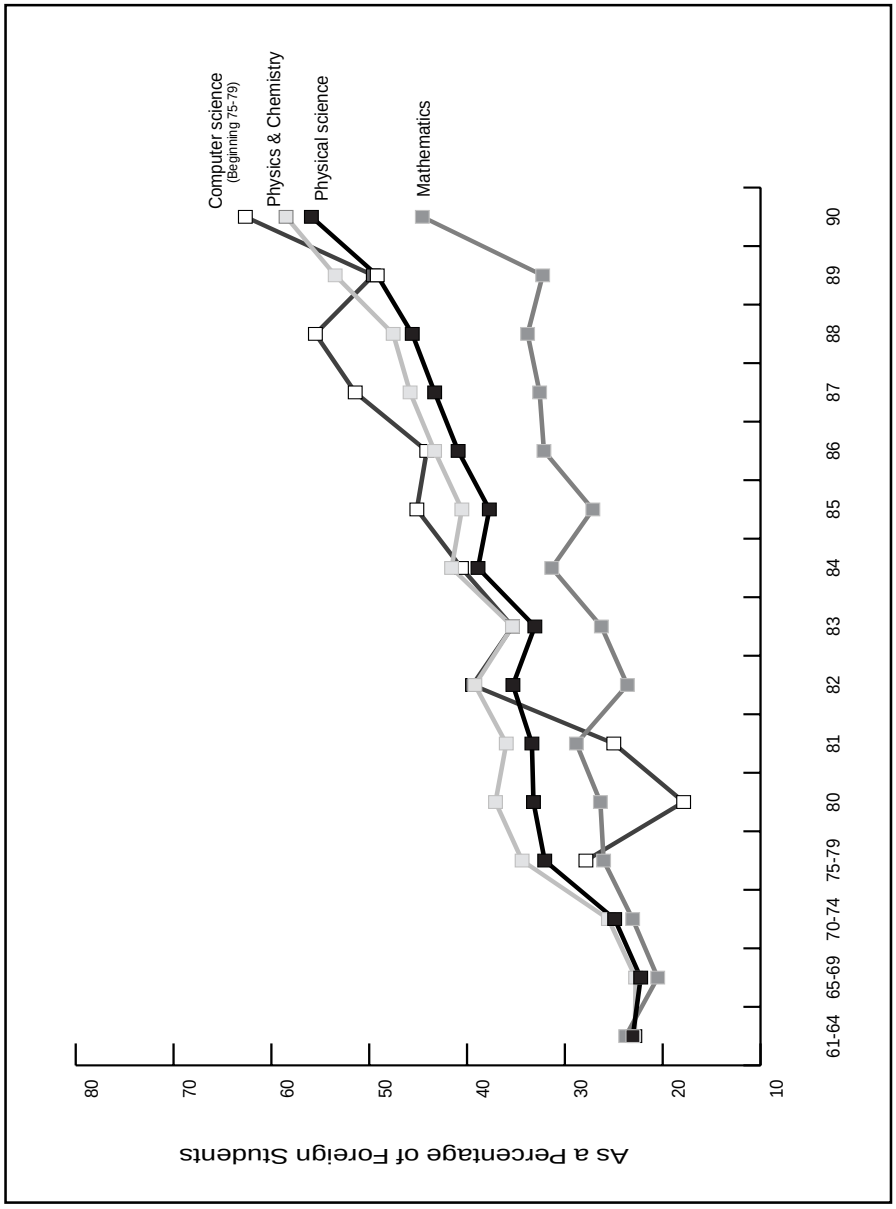
Top Four Asian Countries with American Doctorates



The figures are almost as high for the elite schools of China—Peking University and Tsinghua University[6]

From these countries' perspective, the flow to the U.S. from these elite insti-tutions has increased significantly. At least, 70 percent of their graduates now leave for the United States. For the IIT, the figures are about 85 percent. About 30 percent of all IIT graduates, since its founding in 1954, currently are in the U.S. (Ananth, Babu & Natarajan 1989; Bhagwati & Rao 1996b).

It also is worth noting that the *quality* of students turned out by these elite foreign institutions has increased over time, in turn increasing these students' ability to compete against native students. In 1964, there were 18,000 applications for the 2,000 places at the IIT in India. By the end of the 1980s, applications for these places had increased to 100,000 (Bhagwati & Rao 1996b)!

Moreover, this phenomenon of a rising and high share of foreign students in our graduate programs has surfaced differentially in the S&E (also in the mathematics and economics) programs. Why has it not arisen equally in the "professional" schools of law and business?

Part of the reason lies, of course, in the fact that the "source" countries themselves have not allocated equal energies and financing to attract their most talented students into these professions, as against the S&E, programs.[7]

But the principal reason is that the qualified and talented students from these source countries face a major liquidity constraint. Tuition at the gradu-ate schools in the United States is generally beyond their financial capabilities.[8] Besides they do not qualify for U.S. governmental and bank loans.

[6] Figures provided by the National Research Council (Ries & Thurgood 1993; Thurgood & Weinman 1991).

[7] Such exceptions as the two Indian Institutes of Management and the famous All-Indian Institute of Medical Sciences in New Delhi must be mentioned.

[8] According to a *Wall Street Journal* (Lee 1955) story on applications at top business schools, the price of an MBA rises to as high as $60,000 for two years at private schools.

As it happens, graduate programs in the U.S. have different financial aid possibilities. Professional schools (law, business, and medicine) offer very little financial aid; only 1 percent of the entering class receives primary support from the university. Only somewhat better are the Ph.D. programs in the humanities and education: 20 percent of the students in non-S&E programs receive financial assistance from the university. A striking contrast is offered by S&E Ph.D. programs; more than 70 percent of the students (and 80 percent of the foreign students) in S&E Ph.D. programs list the university as the primary source of financial assistance (Ries & Thurgood 1993). This picture is reinforced when we look at **Figure 5** that shows alternatively the source-composition of support in different fields for doctoral students. University sup-port, reflecting labwork and other research assistance, clearly is a much more important source of support in Engineering, Physical Sciences, and Life Sciences than in the Social Sciences, Humanities, and Education.

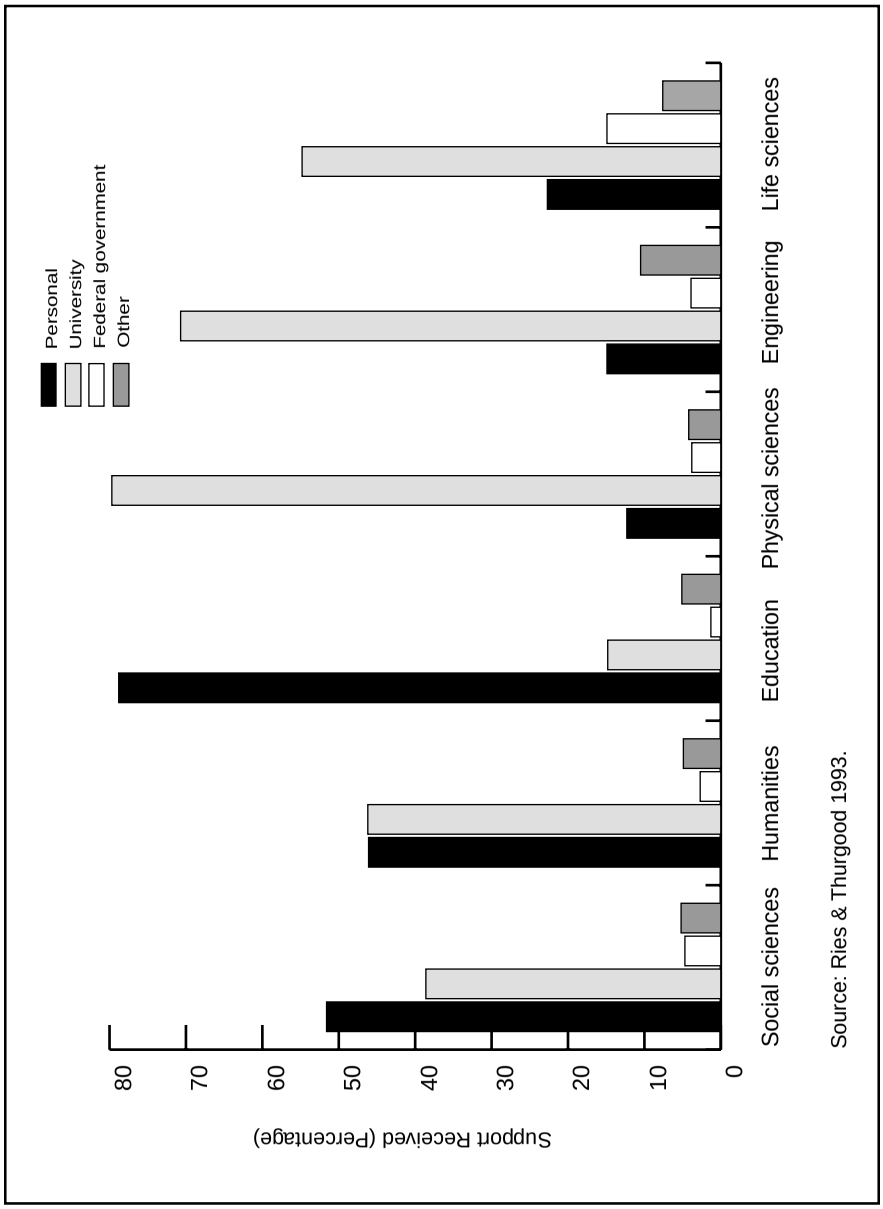
To explain the increased share of foreign students in S&E Ph.D. programs, the foregoing analysis of the factors augmenting the supply of qualified foreign applicants into these programs is not entirely sufficient. Of course, the explanation does not require but would be strengthened if we also could argue that the supply of *native* applicants into these programs has shrunk. But we do need to dismiss the possibility that the native supply of comparably qualified and talented applicants also has not increased simultaneously.

This seems wholly reasonable to assert. There is no counterpart in American education, prior to graduate school, to the factors augmenting the supply of foreign student applications in S&E graduate programs. At the same time, the common complaint is that the starting salaries and possibly even the rates of return to "professional" education—MBAs, medical and law degrees—have attracted growing proportions of the best graduating native students.

POLICY IMPLICATIONS

Our explanation of the rising share and predominance of foreign students in the S&E graduate programs then shows that

Figure 5.
Support Sources for Doctorates
Different Fields, 1991: Total Students



Source: Ries & Thurgood 1993.

it reflects "supply" factors that are critically tied into the meritocratic and non-discriminatory approach underlying U.S. graduate school admissions. The implications below then follow.

The meritocratic approach to admissions to graduate programs results in their attracting the best talent and the best trained candidates from around the world. While itself a reflection of the scientific and academic strength of these programs, it reinforces that strength in turn. The increased influx of talented foreign students into S&E, mathematics, and economics Ph.D. programs is a sign of strength, not of weakness.

The general notion that the share of foreign students is rising because native students are "no longer interested in" S&E Ph.D.s and careers lacks force. At minimum, it omits the Prince from *Hamlet.* The rising share of foreign students reflects the dramatically increased supply of competitive foreign students. The decline in the supply of competitive native students, even if true, is at best a minor part of the story. As admissions are not wholly inelastic, it is worth noting that the overall graduate S&E admissions of natives have not fallen as the admissions of foreign students have risen.

The increased supply of the foreign students as a source of the phenomenon of their rising and risen share in S&E Ph.D.s also implies that the responsive-ness of such graduate production to a fall in the rate of return to such education is likely to be very low. Hence, one could predict sharp falls in these rates of return and "surplus" production without the normal corrective mechanism provided by the fact that the students will simply walk away from enrolling in these programs and, thus, reduce the output of Ph.D.s to levels at which better and competitive rates of return are restored.

This is because foreign students will compare their rates of return from S&E Ph.D.s in the U.S. to the much inferior rates of return to staying or returning home. The earlier-cited RAND-Stanford study of the "excess demand for Ph.D.s in many science fields" (Browne 1995) argues that currently a science doctorate yields a one-in-four chance of not getting suitable employment: ". . . universities in the

United States are producing about 25 percent more doctorates in science and engineering fields than the United States economy can afford." But a rate of return here that is diminished by one-fourth will still exceed the alternative rates of return at home. This also is partly because the direct cost of graduate schooling in the U.S. is substantially taken care of by financial support (usually linked to labs and projects).

Thus, the prospect of quick reversal of "surpluses," such as the one described in the RAND-Stanford study, is diminished. But why should we worry? The effect of such a "surplus" is certain to force one-in-four (if that estimate is properly arrived at and argued plausibly to endure) eventually to work their way downstream to jobs below their expectations. But, as these Ph.D.s cannot find jobs at such places as Stanford, MIT, Caltech, and Bell Labs and, therefore, go downstream to smaller colleges and lesser institutions, they upgrade the quality of instruction and research at these institutions.[9] Surely, that is a reason for us to rejoice rather than lament.

Nor do we need to worry that we are becoming "too dependent" on foreign students. They typically stay on, are even called "stay ons" in the immigration literature! Even when Ph.D.s go back to their home countries, they often return. Professional markets are heavily globalized now and one often gets either "yo-yo" immigrants or migrants who, having returned home or gone elsewhere, eventually come back here to the magnet country they chose in the first place for their graduation into a Ph.D.[10]

As is well-established in immigration studies, few nations can match the facilities for professional research and advancement that the U.S. offers. Nor can other nations match the opportunities that are open to second-generation children in

[9] The downstreaming model is at the heart of the analysis of education in the context of an alternative paradigm to the "human capital" and other theories of education (Bhagwati & Srinivasan 1975). It has been utilized in the context of the theoretical analysis of international migration of professionals (Hamada & Bhagwati 1976).

[10] While we stress here the advantages to us of foreign students "staying on" in the U.S., there also are many indirect advantages to us when and if they return home.

the United States. Just imagine bringing up your children in Tokyo instead of New York or in Kobe instead of Austin. It's no contest.

Foreign students typically see their U.S. education as a stepping stone to immigration into the U.S.[11] Since the 1965 Immigration Act, which opened up a number of "preferences" for admissions of Professional, Technical, and Kindred [PTK] immigrants, this incentive for foreign students to acquire first-rate U.S. degrees and to improve their ability to stay in the United States thereafter has been a powerful one.[12]

The fear that foreign students will disappear from the U.S., leaving us with inadequate scientific personnel, often is expressed or lies behind exhortations to encourage natives to go for S&E Ph.D.s. But, if these students stay on, for the most part, the fear is misplaced.

The United States is uniquely a country of immigrants. There is enormous ethnic diversity in the country. Naturalization is the easiest in the world. The distinction between "us" and "them," directed against foreign students, is wholly incongruous with the country's history and culture. It also flies in the face of the

[11] See Hamada & Bhagwati (1976) where educational enrollment by foreign students in the U.S. was first described as an instrument for immigration, rather than as a method of human capital formation. Numerous instances exist of students from first-rate foreign institutions coming to third-rate U.S. universities, the only motive being to acquire the qualifications that makes immigration less difficult.

[12] Broadly speaking, a nonrefugee foreigner can immigrate legally to the United States under one of two principal categories: family-based or employment-based. The former requires "sponsorship" by a U.S. citizen family member. The latter requires sponsorship by an American employer. The Department of Labor must, on the basis of an American employer's sponsorship, certify that "no American can do or is available for this job." The Department of Labor regulations provide, in addition, for special handling of labor certification applications for college or university teachers; an employer can select the best qualified candidate, regardless of citizenship, for the position.
Hence, for those without U.S. citizen family members, the only feasible route to immigrate legally to the U.S. is to secure employment certification from an American employer. And this route is much more readily travelled when one has a U.S. graduate degree.

culture of excellence and nondiscrimi-nation that has characterized and enriched the American educational scene.

In light of these considerations, we disagree with the reported view of Dr. Phillip Griffith, Director of the Institute for Advanced Study at Princeton and Chairman of a recent study conducted by the National Academy of Science, that "since foreign students account for a large proportion of graduate enrollments, he and his colleagues [would] urge better science education so that even more Americans will be drawn to Ph.D. training" (Greenberg 1995).[13] Getting young Americans to appreciate science is a laudable objective; but surely it is not to be urged because we have foreign students in S&E Ph.D. programs.

Our analysis suggests, contrary to the agitation about the current "surpluses" of S&E Ph.D.s and about the prepon-derance of foreign students in these pro-grams, that the foreign students phe-nomenon is not a problem. Rather, it benefits the country. Other nations' "brain drain" is our "brain gain."

Instead of curtailing the inflow of these talented foreign students or trying to reduce their share in S&E Ph.D. programs, we ought to make their immigration easier, so that we reap the benefits to us from their settling here.[14] Towards this end, we propose that the immigration of S&E Ph.D. students from several designated high-performance institutions should be practically automatic, their abundant *human* capital justifying their immigration, just as immigration law permits those bringing substantial *financial* capital to immigrate readily. That could reverse the balance in favor of importing the talented, rather than the rich, bringing us closer to the ideas that built this nation.

Finally, we must turn to a question that bothers many black leaders: Is the entry of foreign students harming the entry of

[13] We should stress that Dr. Griffith's views (conveyed in personal communication) concerning the desirability of foreign students in S&E programs are thoroughly consonant with ours.

[14] These benefits accrue to us in numerous ways, for instance, through the spillover effect of their ideas and research (Bhagwati & Rao 1994a; 1996a; 1996b).

blacks into our S&E Ph.D. programs? Some in the black community express the view that blacks are being "crowded out" by foreign students (e.g., Morris 1993). Our view is that this argument is incorrect (see also: Bhagwati & Rao 1996b).

The facts on black students are of course alarming (National Science Foundation 1991b:310; 1994a:318). Of the 36,027 Ph.D.s in all subjects awarded in 1990, only 320—less than 1 percent—were awarded to black men; and 508, or just more than 1 percent, were given to black women. Even more ominous is the trend: the number of blacks getting Ph.D.s in all subjects has dropped since 1977. This contrasts strikingly with the experience regarding foreign students highlighted above. But the inference that foreign students come at the expense of blacks is unwarranted.

To begin with, we must reject the notion that there are a fixed number of places in graduate programs and, therefore, that an increase in the numbers of foreign students must be at the expense of natives—black or otherwise. The facts show that the supply of places in graduate S&E programs, which attract the greatest concern, is not rigorously fixed. Over the past two decades, the number of natives in these Ph.D. programs has remained constant (at about 13,000). The Ph.D. programs have, thus, expanded in size as foreign students have increased (National Science Foundation 1991b:310). Thus, there is no *prima facie* presumption that the increase in the numbers of foreign students in these Ph.D. programs has been at the expense of natives.

Could we then argue instead that the black students are crowded out in a financial sense, that the limited financial support available in the universities for their Ph.D. programs is competed away by better-trained foreign students and would otherwise be available to the black students (e.g., DePalma 1992)? We do not think so.

At first glance, of course, the "crowding out" thesis appears plausible as, unlike most foreign students, most black graduates do not receive extensive finan-cial assistance from the universities. In 1990, 69 percent of all foreign graduate students were supported by the universities,

whereas only 25 percent of all black graduate students received grants and assistantships (National Science Foundation 1994b:301).

But this contrast is mostly explained by the fields of study of the two groups (National Science Foundation 1991b:310; 1994a:318). Thus, 81 percent of foreign graduate students are in S&E Ph.D. programs; only 14 percent of black graduate students are in these programs. Most black graduate students are in humanities and, especially, in education Ph.D. programs; more than 50 percent of black graduate students are in education graduate programs. As it happens, graduate programs in the U.S. have different financial aid policies (National Science Foundation 1994a:318; 1994b: 301). S&E graduate students are over-whelmingly supported by their univer-sities; more than 70 percent of the students in S&E Ph.D. programs list the university as a primary source of finan-cial assistance. In contrast, only 25 percent of the students in Ph.D. programs in the humanities and a mere 13 percent of the students in education Ph.D. pro-grams receive financial assistance from their university.

Hold the field of study constant, and the disparities in financial assistance awarded by the universities greatly diminish, indeed virtually disappear. Black American students in S&E Ph.D. programs do receive primary financial support from the university; for instance, more than 70 percent of black graduate students in the physical sciences receive primary support from the university (Thurgood & Weinman 1991).

Besides, much (about 40 percent) of the financial support in S&E comes in shape of research assistance in federally supported projects; the S&E share is more than 75 percent of such support (National Science Foundation 1994b:301). These projects are funded by the Department of Defense, Department of Energy, NASA, and the National Science Foundation. These awards generally go to those who are best prepared to undertake the research, including, of course, black students.

On the other hand, federal “affirmative action”-based funding, for which foreign students are ineligible, is based on different criteria and awarded and administered

by different government agencies—the U.S. Department of Education, in particular—as well as the Higher Education Opportunity Program [HEOP] funded by the states. The budget for this type of aid is distinct from, and not in the least affected by, the federal "projects-oriented" grants. The latter, where the foreign students predominate, does not cut into the former, where the black students do.

Most telling, the numbers of black Americans securing S&E Ph.D.s—precisely the fields to which foreign graduate students flock—actually have increased over the past two decades (National Science Foundation 1991b:310). Hence, while the total number of Ph.D.s awarded to blacks did, indeed, fall from 999 in 1975 to 828 in 1990, in engineering they increased from 11 in 1975 to 28 in 1990, in life sciences from 56 in 1975 to 63 in 1990, and in social sciences from 153 in 1975 to 172 in 1990.

The real problem appears to be that the pool of black students that the Ph.D. programs draw upon is small and, worse, getting smaller (National Science Board 1991:1). The number of blacks securing baccalaureate degrees in S&E actually fell slightly, from 18,700 in 1975 to 18,400 in 1990 (so that the fraction of black S&E baccalaureates who secured Ph.D.s actually *increased*). And, this occurred during a period when the total number of baccalaureate degrees in S&E awarded in the U.S. *increased*; so the proportion of blacks in these areas decreased signifi-cantly. Evidently, the problem for the black community arises at levels *below* the graduate S&E programs; its solution, therefore, will not lie in restrictions on the number of foreign students or on their access to financial support at the graduate level.

EXECUTIVE SUMMARY

Each of the most recent major amendments to the Immigration and Nationality Act includes a requirement for the federal government to assess the environmental impact of alien immigration on the United States. Specifically, the Immigration Reform and Control Act of 1986 [IRCA] specifies that the Triennial Report to Congress shall provide a ". . . description of the impact of immigration on environmental quality and resources . . ." (Sec.401(b)(3)). The Immigration Act of 1990 gives the Commission on Legal Immigration Reform the mandate to consider the ". . . social, demographic and natural resources impact of immigration . . ." (Sec.141(c)(1)(C)).

The goal of this report is to contribute to this area of policy analysis by reviewing existing scientific literature concerning immigration and environment, to identify research issues emerging from extant scholarship, and to develop recommendations for areas of needed research that will benefit the immigration policy process. It is important to note at the outset that remarkably little hard evidence exists about the environmental effects of alien migration on the United States. A great deal of speculation exists about the nature of the relationship and there is increasing popular commentary about the degree to which immigration is associated with environmental problems in local areas as well as in the nation as a whole. The direct or causal effects of U.S. immigration on the environment have not been established, however, through scientific study. Moreover, there are significant limitations in U.S. statistics on immigration and population for the study of environmental impacts.

The report is organized around four dimensions of the research process that are relevant for examining the relationship between U.S. immigration and environmental issues. First, the section, *Perspectives on the Role of Migration in Population-Environment Dynamics,* considers the relevance of theories of population and environmental change for the study of immigration and its effects. Second, the section, *Empirical Research Concerning Migration and the Environment,* reviews the results of research relevant for the study of immigration and environment. Third, the section, *Methodologies for Assessing the Environmental Consequences of U.S. Immigration,* briefly reviews selected approaches to measuring environmental impact. Fourth, the section, *Information Requirements for Studying the Environmental* Conse*quences of U.S Immigration,* outlines strengths and weaknesses of the federal statistical system for

analyses of the role of immigration in population and environmental change. Recommendations for needed research are presented at the end of each section. The *Conclusions* section reviews research issues and priorities within the context of a national program of research on U.S. immigration and environment.

Perspectives on the Role of Migration in Population-Environment Dynamics

The general model of environmental impact identifies three broad sets of factors influencing environmental change: *Environmental impact* [I] is conceptualized as a function of *population* characteristics [P], patterns of *consumption* [A, for affluence] and *technology* [T], the use and manipulation of energy and other natural resources. While this model has provided an organizing framework for much of the debate concerning population and the environment, it has also been criticized for incomplete conceptualization of the components and lack of grounding in social scientific theory. The degree to which the population concept is well specified or connected to theory is also contested: uses of the model focus primarily on the increase in population size without specification of the different sources of population growth, for example natural increase (births minus deaths) relative to net migration.

Theories on population and environment vary in assumptions about the relative importance and direction of the effect of each of the factors (P,A,T) as well as the significance of interrelationships among the factors. Neo-Malthusian perspectives emphasize the significant influence of population growth for environmental impact and conceptualize a negative relationship between population growth and the availability and, increasingly, the quality of environmental resources. In constrast, more "optimistic" perspectives emphasize the enhanced potential inherent in positive population growth for social, economic, and technological progress, and hence, the means to solve environmental problems. Primary importance is given to changes in technology and social and economic organization in mitigating the effects of the other two factors. A third approach conceptualizes population pressure and short-run negative effects as a stimulus to technological innovation and more effective use of resources.

Perspectives thus vary in the degree to which population is proportional to envi-

ronmental change. According to the demographer Keyfitz:

If all else is equal, action damaging the environment is directly proportional to the number of people. That at least seems the most appropriate initial hypothesis. . . . The burden of proof is one anyone who argues against the proportionality hypothesis in either way. (Keyfitz 1993: 547)

In thinking about the impact of alien immigration on the U.S. environment, relevant questions center on the degree to which the impact of alien migration is proportionally less than, greater than, or equal to the number of immigrants.

Not surprisingly, different theoretical perspectives lead to different conclusions about the national and regional environmental impacts of U.S. immigration. Some economists have emphasized the potential contributions to human capital and the potential for technological innovation deriving from positive population growth in the United States and from alien immigration. Many ecologists, in contrast, highlight the role of alien immigration in U.S. population growth with its negative environmental consequences and often focus on the contribution to future growth resulting from the descendants of current immigrant streams.

In addition to the need to specify more clearly the role of migration in theories of population and environment, several additional issues emerge from the review of theory. Both geographic level and temporal frame of analysis must be specified in theoretical models and ultimately in empirical research. The effects of immigration on environmental processes may be expected to be significantly different for metropolitan areas, rural communities, states, and in the short-term versus the long-term. A third issue is the importance of understanding linkages or connections among geographic areas, economic sectors, and through time. For example, the concentration of immigration in certain metropolitan areas in the United States may have environmental consequences for areas and natural resources geographically removed from the cities.

The most fundamental recommendation for theory development is to revise models of population and environment to break population growth into its component parts in order to consider more clearly the effects of migration. Of particular relevance for the United States, moreover, is the specification of effects for different types of international population movements, including permanent resettlement, refugee migration, tempo-

rary labor migration, and tourism, within theories of environmental impact.

Empirical Research Concerning Migration and the Environment

There is a strong and long tradition of research on the consequences of immigration for U.S. society, economy, and polity. Scholarly interest in the environmental consequences of U.S. immigration has a relatively more recent history, originating in the late 1960s with environmental concern over national population growth and the role of annual alien immigration in the path to population stabilization.

There is increasing interest among scientists and policymakers in the environmental implications of immigration for states, metropolitan areas, and local communities in the United States. Most research to date, however, tends to focus either on population growth and trends in alien immigration, viewed as the causes of environmental change and problems, or on the environmental outcomes of interest, such as land use patterns and urban sprawl, water supplies and quality. Social demographic research is being conducted concerning the role of alien immigration in metropolitan and regional growth patterns in the United States. Inferences about environmental impacts resulting from alien migration are often drawn without direct measurement of the relationships between the two sets of factors: patterns of population growth and immigration are observed to co-vary with environmental outcomes, while data on causal relationships are not presented. Similarly, environmental research often focuses on direct measurement of environmental processes and quality with only cursory measurement of population and social processes that are set out in the introductory statements as direct causes of environmental change.

In short, there exists very little direct causal analysis of relationships among population, immigration, and environment in the United States. Virtually no research has been conducted on the role of immigration status or nativity in the analysis of consumption and production, such as differential patterns of energy consumption, commuting and land use patterns, and water conservation practices.

Probably the best research on migration and environmental outcome has been conducted in areas of the developing world. Very often these are case studies of the complex relationships among migration,

social, economic and technological change and environmental processes. These studies may serve to inform conceptual models, research design, and measurement in empirical studies of population, migration, and the environment in the United States.

The general observation concerning the status of empirical research on U.S. immigration and the environment is the need for more of it. There is critical need for the initiation of well-designed studies that will yield both descriptive information concerning trends and patterns of demographic and environmental processes in U.S. states and local areas, as well as causal analyses of the relationships between types of alien immigration and environmental impacts. It is particularly important that research on the environmental effects of immigration identify different sources of alien migration, for example, permanent resident aliens, foreign students and workers, and tourists. This significance of subsequent internal migration among immigrants should also be studied.

Methodologies for Assessing the Environmental Consequences of U.S. Immigration

Two frameworks that have been developed to study environmental change are relevant for the study of U.S. immigration and the environment: environmental impact assessment [EIA] and population-environment monitoring systems [PEMS]. Environmental impact assessment most often attempts to forecast the impacts of development projects or structural or engineering initiatives, generally new activities within a geographic area. Monitoring systems represent ongoing social and environmental accounting frameworks for the collection and analysis of data over time for specific geographic areas.

The goal of the EIA process is the provision of objective, typically quantifiable, information for policymakers and program administrators concerning the range of environmental consequences of some proposal, often a building project, for a region or place. Inherent in the EIA process are theoretical models of the nature

of causes of environmental change. It is important to place the proposed source of environmental change, i.e., the project or policy initiative, within a multivariate framework in which all exogenous influences on environmental outcomes are documented. The process of EIA involves predictive and, thus, causal analysis. The approach may be useful in assessing various immigration policy options, for example, changes in overall levels of annual alien immigration to the United States, as well as changes in the structure of immigrant admissions in terms of individual and family characteristics.

Population-environment monitoring systems measure changes in these factors over time and are useful in providing an empirical foundation for evaluation of existing policies and collecting baseline data for identifying subsequent environmental impacts. If the approaches to monitoring are standardized across administrative units, results of PEMS can be compared among local areas and also aggregated for analysis of regional dimensions of national policies. This characteristic of PEMS is critically salient for purposes of U.S. immigration policy evaluation.

A critical issue in exploring the use of EIA or PEMS for the study of immigration and environment is the degree to which the assessment or monitoring system documents all significant dimensions of environmental impact for the regions. Beyond the contribution of alien immigration to population growth for a region or area are issues concerning patterns of resource consumption, technological innovation, conservation behaviors, land use patterns, and how these vary between immigrants and U.S. residents, and among types of immigrants. Moreover, the methodologies must be open to document other sources of environmental impact for the study area, such as in- and out-migration of U.S. residents and economic change. Finally, the relevance of any EIA, monitoring system, or other more appropriate research design for determining the effect of U.S. immigration on the environment will rest, finally, in the degree to which *national, state,* and *local* data collection systems can support multivariate analysis of complex dimensions—demographic, economic, institutional, behavioral—of environment change.

Information Requirements for Studying the Environmental Consequences of U.S. Immigration

The specification of data needs should be guided both by theory and by the important policy questions concerning U.S. immigration and the environment. While the emphasis of this report is generally on the relevant research concerning immigration, it is important to note the serious concern among environmental scientists about the status of environmental data for the United States and the capacity for monitoring environmental quality and resources for different geographic areas.

Fundamental to the analysis of immigration and the environment, however, is statistical information on the contribution of alien immigration to population growth for states, regions, cities, and local communities in the United States. Further, because the present policy debate concerns the impact of *alien* migration, disaggregation of the components of population growth—fertility, mortality, and migration—by immigration status is also a necessary characteristic of statistical information. Accordingly, the report focuses on the adequacy of U.S. data on population processes for measuring the role of alien immigration in population dynamics on national, regional, and local scales of analysis.

Problems in the adequacy of national demographic accounts for the comprehensive measurement of trends and components of population change have been well documented. Three sets of issues pose particular problems for the empirical evaluation of the role of alien immigration in population growth and generally in environmental processes. First, conceptual problems exist in official data on alien immigration. U.S. statistics on immigration collected by the U.S. Immigration and Naturalization Service [INS] represent legal and administrative categories, including permanent resident alien, nonimmigrant, refugee, asylee, and parolee. As a result these data are less than ideal measures of demographic concepts of long and short-term immigration that use criteria such as length of stay and activity in the country. Work has been done to manipulate INS administrative data better to represent demographic concepts of alien immigration. Comparison of demographic measures with official INS data on admissions yields important differences in the national origins characteristics of annual alien immigration to regions and states in the United States.

Second, U.S. statistics on international migration lack closure: it is not possible to assess the impact of alien immigration on population growth in an area if not all sources of population change are known. For example, no systematic source of data exists on the process of out-migration of

aliens or citizens from the United States; measurement of levels and patterns of undocumented migration relies on demographic estimation. Very useful work has been conducted by the U.S. Census Bureau to estimate emigration using census and survey data. There has also been consideration of other federal sources of administrative data as a basis for estimating emigration. As with alien emigration, estimates of undocumented migration have been developed using methods of demographic estimation for U.S. census data, immigrant data records, and assumptions about mortality levels, emigration, and census undercount. Demographers at INS have also estimated the size of the undocumented alien population by state of residence.

Third, the role of alien migration in annual population growth for states and local areas is not easily measured. Decennial census data are extremely valuable for measuring components of population change for small geographic areas at ten-year intervals. Currently, however, annual measures of the immigrant population at the subnational level are available for large states and metropolitan areas through the Current Population Survey. The lack of data on internal migration patterns of immigrants is particularly frustrating for comprehensive study of the effect of immigration on states and local areas.

Longitudinal survey design holds strong potential as a means more effectively to collect data on the social demographic behavior and experiences of immigrants and U.S. citizens relevant for the study of immigration and environment. The research community has recognized the value of a survey of immigrants to directly study patterns of settlement and internal mobility among immigrants, as well as social characteristics and economic behavior among immigrant cohorts and how these change over time. To yield results appropriate to environmental research, survey design must address, first, the need for reliable data at different geographic scales, and, second, the critical need to compare environmental relevant behaviors and characteristics among different groups of immigrants and with U.S. citizens over time.

Conclusions

Four broad areas of recommendations for scientific research concerning U.S. immigration and environment emerge from this review:

First, research on the environmental consequences of U.S. immigration will benefit from the revision of models of the population-environment to specify the role of migration and, specifically, types of

international migration, in processes of environmental change. Theoretical development concerning migration and the environment needs to occur to derive relevant and testable hypotheses about causal relationships and effects.

Second, research on U.S. immigration and the environment should provide both descriptive results concerning trends in demographic and environmental change at different geographic scales and for specific places, as well as causal insights about the nature of relationships between levels and types of alien immigration and environmental outcomes. Studies should be undertaken on the national, regional, and local levels to compare the effects of immigration at different geographic levels, adding to our understanding of geographic variation of impacts.

Third, it is critical that attention be given to developing the necessary research designs for ongoing study of the interrelationships among population, immigration, and environmental processes for the nation, states, and local areas in the United States. Survey methodology has been shown to hold useful potential for studies of the social and economic consequences of migration and should be explored for studying environmental impacts.

Fourth, the statistical foundation for the analysis of the environmental consequences of U.S. immigration must be strengthened. Migration statistics—data on alien immigration, internal migration, and emigration—must be improved to accommodate local and regional analysis for intercensal periods. As relevant in these times of fiscal restraint in federal spending is the critical need to advocate the continuation and maintenance of current statistical programs: INS statistics on the admission of aliens to the United States must continue to be collected and made accessible for public use; questions concerning nativity, citizenship, and geographic mobility must continue to be asked on the decennial census and the Current Population Survey. Finally, an assessment of the status of indicators of environmental quality and resource availability is a critical component of developing an agenda of policy relevant scientific research.

These broad recommendations beg the question of strategy for stimulating and organizing research efforts to address the important analytic issues concerning U.S. immigration and the environment. Interdisciplinary collaboration is essential for the development of a research program on U.S. immigration and the environment. Interaction among environmental and

social scientists in government agencies and planning offices, as well as in universities and research institutes, must be encouraged to initiate theoretical development, to reflect on research design, to document the status of available data, and, ultimately, to establish a framework for interpretation of research results in connection to the policy process.

Given the need for both baseline documentation and exploratory analytic research, it seems highly appropriate to initiate a coordinated research program on immigration and environment for specific regions, metropolitan areas, and local communities in the United States. Selected places should be identified as research sites in which an integrated program of population and environmental research would be implemented. Interdisciplinary collaboration among scientists must be organized within research sites and coordinated with relevant planning and scientific agencies at the federal, state, and local areas.

A Final Observation

Barry Commoner once stated that he knew ". . . of no scientific principle which can tell us how much to rely on population control and how much on technological change (and the required economic controls) in order to reduce environmental impact. The choice between these alternative paths is clearly a political one, not a matter of science." A somewhat contrasting perspective is evident in this report. Research on relationships between U.S. immigration and the environment is an essential component of rational and responsible decisionmaking concerning U.S. immigration. Whether environmental criteria are appropriate grounds for revising immigration policy encompasses questions that are within the grasp of social and environmental research.

INTRODUCTION

Each of the most recent major amendments to the Immigration and Nationality Act includes a requirement for the federal government to assess the environmental impact of alien immigration on the United States. Specifically, the Immigration Reform and Control Act of 1986 [IRCA] specifies that the Triennial Report to Congress shall provide a ". . . description of the impact of immigration on environmental quality and resources . . ." (Sec.401(b)(3)). The Immigration Act of 1990, which focused on legal immigration, gives the Commission on Legal Immigration Reform the mandate to consider the ". . . social, demographic and natural resources impact of immigration . . ." (Sec.141(c)(1)(C)), and also requires the government to provide statistical information that is ". . . useful in evaluating the social, economic, environmental, and demographic impact of immigration laws . . ." (Sec.142(c)(1)).

These statutory mandates to consider the relationship between U.S. immigration and environmental processes and issues provide an opportunity for social and environmental scientists to expand theoretical and empirical knowledge concerning population-environment dynamics by giving specific attention to processes of international migration, mobility, and circulation. The goal of this report is to contribute to this area of policy analysis by reviewing existing scientific literature concerning immigration and environment, to identify research issues emerging from extant scholarship, and to develop recommendations for areas of needed research that will benefit the immigration policy process. It is important to note at the outset that remarkably little hard evidence exists about the environmental effects of alien migration to the United States. A great deal of speculation exists about the nature of the relationship and there is increasing popular commentary about the degree to which immigration is associated with environmental problems in local areas as well as the nation as a whole. The direct or causal effects of U.S. immigration on the environment have not been established, however, through scientific study. Moreover, there are significant limitations in U.S. statistics on immigration and population for the study of environmental impacts.

The report serves as an initial review of four salient dimensions of a policy relevant research agenda concerning the relationship between U.S. immigration and environmental issues. First, we consider the relevance of contemporary theoretical perspectives on the relationships among population change, migration, and environmental processes and problems. Sec-

ond, we review the extant scientific literature concerning these relationships. While primary attention is directed to studies pertaining to the United States, the review seeks to be comprehensive by considering relevant research concerning migration and the environment in other countries and regions; particular attention is given to research concerning immigration and the environment in Australia. Third, we consider the relevance of existing methodological approaches to studying environmental change for the analysis of the environmental consequences of alien immigration and international population movements to and from the United States. Environmental impact assessment and population-environment monitoring systems are considered specifically. Fourth, given existing theory and methods, we reflect on the information requirements for analysis of immigration-environmental relationships at various geographic scales in the United States. The degree to which federal statistics can support analyses of the role of immigration in national, regional, and local population dynamics is considered a critical issue for policy research concerning immigration and the U.S. environment.

Throughout the review, we draw on scientific literature specific to the United States as well as studies and perspectives on human environmental impact specific to other countries and regions, including areas within the developing world. We thus attempt to glean from this array of scholarship insights about theory, methods, and empirical research that are relevant for developing a research agenda for the U.S. context. The paper concludes with an outline of research priorities concerning the consequences of immigration for environmental processes and trends in the United States.

A Further Rationale

As implied above, the legislative mandate for information on the environmental consequences of U.S. immigration provides an important opportunity for policy relevant research and also for the expansion of scientific literature concerning population-environmental dynamics. In short, there is an opportunity for both basic and applied research concerning human-environmental interactions. There is also a need for such research because conclusions or inferences about the environmental consequences of immigration may be preceding systematic study of the issues (for example, Mann 1990; Population-Environment Balance, Inc. 1992; Simcox 1992; Federation for American Immigration Reform 1991). It is relevant to note that

the premature use of environmental arguments in debates over immigration was anticipated in Canada a few years ago. The Canada Employment and Immigration Advisory Council observed that given evidence about the positive economic impacts of immigration, the Canadian public might be expected to shift its attention to another rationale to restrict immigration, and that argument could likely settle on environmental issues (see Canada Employment and Immigration Advisory Council 1991:30-31).

It is also interesting to note that the discussions about environmental effects are somewhat reminiscent of the tone of statements made in the early decades of this century concerning the social and cultural effects of immigration, e.g, in such statements as the one below made in 1926 by George Cutten, President of Colgate University concerning the effects of immigration for the quality of the U.S. population and society. [Currently on display in the exhibit on immigration restrictionism at the Ellis Island Museum, perhaps it is not the most appropriate illustration, but it holds intrinsic interest for this writer.]

The melting pot is destructive to our race. . . . We must either build up from own resources and conserve our race power, or else we must admit only such immigrants as shall strengthen and not weaken our race, or both. The danger the 'melting pot' brings to the nation is the breeding out of the higher divisions of the white race and the breeding in of the lower divisions. (Wood 1923)

A recent statement by the Federation for American Immigration Reform concerning the environmental effects of current alien immigration to the United States directs attention to the relationships among immigrant fertility and population growth within the context of declining environmental quality and resources:

WHY A LIMIT?
Our Natural Environment
Says There Must Be Limits
on Increasing Numbers
of Immigrants

> We are plagued by water shortages, overflowing landfills, crowded transportation systems, deteriorating wilderness and recreation areas and toxic pollution, ailments that point very clearly to the fact that the U.S. is overpopulated. . . .
>
> Some experts point to the increasing number of immigrants and refugees admitted to this country during the last ten years as one reason for the rising

> fertility rate. Most of the recent entrants to the U.S. have come from countries with high fertility rates, and many who come are in their childbearing years. . . . (Federation for American Immigration Reform 1991:41-42)

Even somewhat more scientific accounts of U.S. immigration draw illusions to ecological concepts. Note, for example, the reference to limits on the absorptive capacity in a recent publication of RAND-Ford Foundation Program for Research on Immigration Policy:

> **Policy Questions Regarding the Flow of Immigrants**
>
> Policies of the last decade leave three central issues regarding new immigration unresolved.
>
> **Aggregate Total Numbers**. Each of the three significant immigration measures passed by Congress during the 1980s has been considered independently, and each has had an expansionary and compounding effect on the size of legal immigration. For the most part, each has been considered without a unifying debate on the overarching question of how much total immigration . . . the nation can productively absorb. Of particular note, policy makers have not examined the ***absorptive capacity*** of the major metropolitan receiving centers.
>
> . . . The policy question will be how to respond to the growing pressures [for immigration to the United States]: Is there a ***limit*** to the nation's ***absorptive capacity*** , and , if so, what is the ***limit?*** [emphasis added] (Rolph 1992:50-51)

These are appropriate questions reflecting ecological perspectives concerning the human environment. While Rolph does not define explicitly absorptive capacity, we can infer the concept to refer to the capacity of societal institutions to receive and integrate alien migrants (as opposed to the addition of native births) into local communities, regions, labor markets, and, ultimately, national society. Absorptive capacity is thus related to an area's carrying capacity [see pages 24-25 below] but encompassing the availability of social, economic, and political resources effectively to accommodate newcomers.

Increasingly, however, there are popular interpretations of the effect of immigration on both the social and physical environment. While questions concerning absorptive capacity are similar to the

above statements, definitive answers are being forwarded identifying immigration as the cause of a range of social and environmental problems. Excerpts from the *San Francisco Examiner-Chronicle* are illustrative:

Bursting at the Seams

> . . . It is time to consider a moratorium on immigration until we have provided a lamentably lacking element in our governance system—a population policy. We need to determine the carrying capacity of the state.
>
> Fiscal problems aside, how many people can our dwindling natural resources support at a reasonable standard of living?
>
> Consider water, for example. As we have learned recently, the filling of the reservoirs by this year's rains will not solve the long-term water shortage.
>
> Even with reservoirs at capacity there is not enough water to satisfy present demands, much less an unending demand for more. The population grows; the water supply does not. . . .
>
> Water conservation can extend existing supplies, but you can only tighten the belt up to a point. A continually growing population will overtake all efforts at conservation.
>
> Another declining resources is topsoil. . . .
>
> . . . Where once there were miles of orange groves beneath snowy mountains, there are now miles of besmogged suburbs, and the mountains are seldom visible. . . .
>
> Half of the state's population increase comes from net births . . . [net increase]. But most of the births that increase the population are attributable to immigration. (Gilliam 1993:7,12)

The point is that statements currently are being presented about the relationships among population, immigration, and the environment in the United States. It is critical that scientific evidence concerning these relationships enter into the policy arena both to inform the immigration policy process and to clarify the multiple causes and correlates of environmental issues. As Preston (1993:601) observes, "[d]iscussions of appropriate levels of im-

migration inevitably will become heated, and it is important to begin now to establish a sound basis for any revisions."

PERSPECTIVES ON THE ROLE OF MIGRATION IN POPULATION-ENVIRONMENT DYNAMICS

Introduction

Theoretical perspectives on the relationship between population and the environment generally fall into three broad camps, each with different implications for policies concerning population regulation and migration. These perspectives have been critically presented by Hogan (1992), Lowe and Bowlby (1992), Fincher (1991:9-16), and Lowenthal (1992, 1990) among others, and will be described only briefly here. Neo-Malthusian perspectives conceptualize a negative relationship between population growth and the availability, and, increasingly, the quality of environmental resources (see, for example, Ehrlich & Ehrlich 1992; Grant 1992). More optimistic perspectives emphasize the enhanced potential inherent in positive population growth for social, economic, and technological progress and, hence, the means to solve environmental problems (see for example, Simon 1990, 1992; Repetto 1987); Boserup conceptualizes population pressure as a stimulus to technological innovation and more effective use of resources (Boserup 1981). A third perspective, less associated with proscriptions concerning population control policies, identifies population growth as a factor that retards efforts at social and economic development and exacerbates social inequality within poor societies (see Mink 1992; Caldwell 1985; cf. National Research Council 1986; United Nations Secretariat 1991).

The general model of environmental impact has been presented and applied by Ehrlich & Ehrlich (1990) among others (see Marden & Hodgsen 1975). Environmental impact [I] is conceptualized as a function of population characteristics [P], patterns of consumption [A, for affluence] and technology [T], the use and manipulation of energy and other natural resources. This model has provided an organizing framework for much of the debate concerning population and the environment. Neo-Malthusians emphasize the significant influence of population growth for environmental impact, while "optimistic" perspectives give primary importance to changes in technology and social and economic organization in mitigating the effects of the other two factors.

The model has been criticized for the incomplete conceptualization of the causal components and the lack of grounding in social scientific theory. Meyer and Turner (1992:52) note that the model ". . . suffers from the handicap of a mismatch between its categories of driving forces (apart from population) and the categories customarily used in the social sciences. Neither "affluence" nor "technology" as defined is associated with a substantial body of social science theory; any bridges between the IPAT and other approaches would have to be built between these categories and those better-conceptualized aspects of behavior and social structure that may drive and limit changes in production and consumption." Demeny (1991:410-12) comments on the implication of independence among the three components of environmental impact and hence the lack of conceptual attention to the ways in which changes in population, consumption and technology are interrelated.

The degree to which the population concept is well specified or connected to social theory can also be contested: uses of the model focus primarily on the increase in population size without conceptualization of the different sources of population growth, for example, natural increase relative to net migration. For example, critical attention to the interrelationships among migration, patterns of consumption, and shifts in technology is not accommodated in the model; in general, testable hypotheses about the effect of population movements on social and technological change are not derived from the model. Relatedly, the model frustrates a dynamic perspective concerning the consequences of changes in the factors over time. Pragmatic considerations of short-term versus long-term relationships are not prominent in the theoretical discussions.

In spite of these conceptual deficiencies, however, the IPAT model has become an important conceptual construct influencing general thinking about population-environment relations. Keyfitz (1993:547) clarifies the strengths and weaknesses of the general model and states the hypothesis clearly:

> If all else is equal, action damaging the environment is directly proportional to the number of people. That at least seems the most appropriate initial hypothesis.

Keyfitz provides examples of circumstances in which population has a more than proportional effect on environmental change, that is, a 1 percent increase in population results in more than 1 percent change in some environmental characteristic, for example, the stock of some natural resource; similarly, one can illustrate

circumstances in which population growth is associated with a less than proportional environmental impact. According to Keyfitz, however, "(t)he burden of proof is one anyone who argues against the proportionality hypothesis in either way" (1993: 547).

Population-Environment Models and Migration

This discussion of general perspectives on population and environment suggest that an appropriate modification of theory is the improvement of the ways in which population processes and concepts are specified. For example, the effect of in-migration on environmental change is likely to be different from the effect of above replacement fertility or of mortality decline, thus, using the vocabulary of Keyfitz, immigration may have a different level of proportionality than other demographic processes. Hence, results specific to demographic behaviors (mortality, fertility, and geographic mobility and migration) will be relevant to different policy responses.

Theoretical discussions of population-environment relationships vary in the degree to which migration is critically considered. For example, neo-Malthusian perspectives give greater conceptual prominence to the negative effects of aggregate (positive) population growth and hypothesize that any source of growth, such as positive net migration, has negative consequences for the environment. The application of these perspectives to the United States, for example, leads to conclusions about the negative effects of alien immigration for preservation of resources and environmental quality. Not surprisingly, more optimistic conceptualizations draw the converse hypothesis about the role of migration on technological and environmental change (see Simon 1990). Fundamentally, however, the role of migration in environmental change derives directly from the underlying conceptual model of population-environmental dynamics: the effect of migration is specified on the basis of its (positive) contribution to population growth.

Among the recommendations of the National Research Council Committee on the Human Dimensions of Global Change was the need to ". . . 'unpack' broad concepts, such as technological change, economic growth, and population growth, that are frequently offered as explanations of how human activities cause global change" (Stern, Young & Druckman 1992:97; see

also Ness, Drake & Brechin 1993b:377-406). Such recommendations hold particular relevance for specifying the role of migration in environmental process and change. For example, in a critique of perspectives on population and the environment, Hogan (1992:113-14) identifies, first, the theoretical disadvantages of the concept of aggregate population growth and, second, the advantages of considering more meaningful demographic processes:

> But in all of these cases [theoretical perspectives], with a pure or moderated or even inverted Mathusianism, what we see is an emphasis on the volume or growth rate of population. The refrain is always the race between population and resources. The question of the population/ resource or population/ environment relation is reduced to a unidimensional relation. the ways in which patterns of fertility, morbidity, mortality, migration, nuptiality, and age structure relate to environ-mental change, have received little attention. What seems to have occurred, on the one hand, is that for the Neo-Malthusians, there is not reason to go beyond this point; the relation is clear, and the solution obvious. On the other hand, the critics look for the causes of environmental problems in other processes. It is as though population growth causes everything or population is unimportant.
>
> What is needed is an analysis of the relationships of demographic dynamics, in all their complexity, with environmental change. . . .
>
> An important starting point in efforts to go beyond such generalizations is to decompose what we mean by "population pressure" which has been nearly universally understood to mean excess numbers with clear conclusions about policies to reduce fertility rates.

Hogan's observation about the derivation of fertility policy proposals is increasingly applicable to policy recommendations to restrict or to promote immigration. Such proposals similarly derive from inherent conceptualizations of the environmental effects of aggregate population growth.

The theoretical necessity to disaggregate the components of population growth in order to specify the role of migration (or any demographic behavior) in environmental processes is reinforced by Mink

(1992) in his discussion of the interrelationships among population, development, and the environment. In reference to developing countries, Mink identifies the range of effects of migration on environment processes that are conditioned by social and economic factors in both places of origin and destination:

> Migration often represents a response to imbalances between population levels and the capacity of local environmental resources to support them. There are also potent environmental impacts in areas receiving the migration, which will differ according to the form the migration takes—whether of individuals or households, seasonal or permanent, to frontiers or established communities—and which can either mitigate or exacerbate the environmental impact of population growth. Some forms of episodic migration, such as flight from political strife, can expose environmental fragile areas to massive population increases . . . (Mink 1992:26-27).

Implicit in Mink's discussion is both an emphasis on the importance of shorter-term effects of migration on developing areas, particularly refugee migration, as well as the importance of incorporating causes and characteristics of migration processes in studies of environmental change. Finally in their critical analysis of population-environment perspectives, Arizpe, Stone, and Major (1994:340) state:

> Population must not be reified as if the simple numbers of human bodies were all that mattered. From the standpoint of population/environment analysis, people are significant in terms of what these humans do in a matrix of social and environmental interactions. This means that population must be understood as a process of biological and social reproduction whose components are principally interactions. Research must focus on these interactions as the relate to the three determinants of population—fertility, mortality and migration.

They emphasize the relevance of study on the relationship between migration and environmental change and the role of gender and income inequality in migration processes and changing environmental processes, such as patterns of consumption, resource extraction, and

waste production (Arizpe, Stone & Major 1994: 339-40).

Perspectives on the relationship between global dimensions of urbanization do focus on the significance of migration as a component of regional population growth and redistribution (see Keyfitz 1991; Berry 1990; Detwyler 1971) but generally in the form of regional rural-urban movements and labor circulation. Perspectives on optimum city size, in contrast, grapple with the effect of the aggregate concept, urban population growth, on urban efficiencies in accessibility of services and resources, and urban environmental characteristics, such as residential and industrial density, air and water quality, pollution, waste disposal, and sewage processing. Less attention is given to the nature of the relationships between specific sources of urban growth, for example, alien immigration versus internal migration, and social and environmental outcomes in urban areas and metropolitan regions, although issues of population homogeneity and urban problems have been raised (see for example, Speare & White 1990, 1992; Fincher 1991; Murphy, et al. 1990; cf. Muller 1993:211-13).

Migration and Global Environmental Change

The degree to which migration processes are considered in conceptualizations of population-environmental linkages is a function of both theoretical perspective and geographic scale of analysis. Perspectives on global environmental change generally focus on overall population growth without significant or specific attention to component processes underlying patterns and trends in geographic distribution (see, for example, National Academy of Sciences 1991; Ehrlich & Ehrlich 1990; Stern, Young & Druckman 1992; Barry, Mather & Sdasyuk 1991; Mathews 1991a; also Royal Society of London and National Academy of Sciences 1992). Moreover, models of global population change emphasize the implications of regional variations in population growth but tend to obscure the role of international or interregional migration in the global outlook and regional trends (see Keyfitz 1991; Demeny 1990; Goudie 1990; Smil 1990, 1991; Bongaarts 1992; also Coale 1975). In this sense, some contemporary perspectives are reminiscent of earlier consider-

ations of population growth for the environment (see, for example, Turk, Turk & Wittes 1972; Waldron & Ricklefs 1973; Detwyler 1971a; cf. Dubos 1971; see also Goudie 1990).

Perspectives on U.S. Immigration and the Environment

Perspectives on the national and regional environmental impacts of U.S. immigration similarly reflect underlying theoretical frameworks. Simon (1990) has emphasized the potential contributions to human capital and the potential for technological innovation deriving from positive population growth in the United States and alien immigration. Short-run costs of immigration are distinguished from long-term benefits; age composition of immigrants, rather than such characteristics as national origin or education, is considered the important policy issue relevant for questions of immigration impacts. Ehrlich and Ehrlich (1992), in contrast, have used the IPAT model to illustrate the degree to which the United States is over populated and the need to constrain population growth. These authors recognize both the long-term benefit of reducing levels of fertility as well as the political and sociological difficulties in recommending the cessation of immigration as a route to stationary (zero) population growth (Ehrlich & Ehrlich 1992:130-31).

Most neo-Malthusian perspectives on the environment, however, generally highlight the role of alien immigration in U.S. population growth and often focus on the contribution to future growth resulting from the descendants of current immigrant streams (see for example, Bouvier 1991, 1992). The results from these studies, often population projections, present images of unending population growth deriving from the rising demand for immigration within developing countries and positive annual levels of permanent immigrant additions. Inherent in these perspectives are critical conceptual and analytic issues concerning immigration and population growth. For example, there is contention over appropriate approaches to conceptualizing the source of population growth resulting from international migration in annual measures of population growth as well as in population projections. Interpretations of population projections must also be resolved with results of formal demographic studies of the relationship between annual immigration and the achievement of a national stationary population.

Conceptual Issues Emerging from Models of Population-Environmental Change

Several analytic issues emerge from this review of the conceptualization of migration in population-environment models. Very fundamentally, the conceptu-alization of immigration as a component of population growth must be revisited. Second, both geographic level of analysis or geographic scale and temporal reference, for example, short-term or long-term, must be specified in theoretical models and, ultimately, in empirical research. The effects of immigration on environmental processes may be expected to be significantly different for metropolitan areas, rural communities, and states. Similarly, the setting of policy goals regarding immigration and the environment and the process of policy evaluation require explicit time frames for analysis and assessment. A third analytic issue is the importance of understanding linkages or connections among geographic areas, economic sectors, and through time. For example, the concentration of immigration in certain metropolitan areas in the United States may have environmental consequences for areas and natural resources geographically removed from the cities.

Immigration as a Component of Population Growth

There is not consensus among demographers concerning the most appropriate approach to conceptualizing, and hence measuring, the proportion of population growth due to migration or the role of immigration in future population growth. For example, partitioning annual population growth among demographic components to yield the proportions (in percents) of growth due to immigration ignores the overall level of population growth and also assumes all sources of population change are measurable (see pages 57-59 below). Warren (1994b) suggests the comparison of annual immigration to total additions to the population, that is, immigrants and births is a more appropriate approach to thinking about immigration's contribution to population growth (see also Keely 1974). Weeks (1992) advocates the migration ratio: net migration as a proportion of natural increase, (births minus deaths) for areas. Simon (1990) argues for the use of the ratio between either the flow of immigration (immigration admissions or arrivals) or the stock

of immigrants (such as the foreign-born population) to the residential population in a given year as a gauge of immigration of both demographic and social impact.

Similarly, there are differing approaches to conceptualizing the impact of immigration on future population growth in both the short and long-run. Population projections simulate future patterns of population growth by making assumptions about changes in behavioral patterns of demographic processes (mortality, fertility, and migration), by age and sex, and often by other social demographic characteristics such as race and rural or urban residence. The effect of the demographic components of growth on future population size and structure (age and sex composition) is shown by comparing the results of different projection series in which different assumption are modelled. For example, the U.S. Census Bureau conducts population projections assuming the continuation of current levels of net immigration (see page 59 below) and projections assuming zero net immigration.

Problems in interpreting the results of population projections concerning the contribution of immigration population growth have been discussed by demographers (see, for example, Edmonston & Passel 1992; Keely & Kraly 1978; Kraly 1981). A fundamental issue concerns the choice of reference data for measuring the demographic impact of immigration: nearly 100 percent of U.S. population growth since 1790 has resulted from immigration and the descendants of immigrants. There are empirical difficulties in developing assumptions about fertility among first and subsequent generations of immigrants. Further, emigration is often not modelled as an age specific propensity, but is subsumed with a concept of net immigration. Given the wide use made of population projections in discussions of U.S. immigration policy issues, it is critical that conceptual issues in both approaches to modelling and in the interpretations of results be clearly set out.

Similarly the results of formal demographic analysis of immigration and population growth should be incorporated into models of population and environment. As mentioned above, there is a solid body of demographic theory that has revealed the relationship between positive immigration and the achievement of population stabilization at zero annual growth, that is, a stationary population (Keyfitz 1971; Coale 1972; Pollard 1973; Espenshade, Bouvier & Arthur 1982; Mitra 1983; Espenshade 1986; Feichtinger & Steinman 1992). A stationary population is consistent with annual immigration given fertility at replacement or below replacement levels. The ultimate size of

the population is a function of the level of fertility and mortality, annual levels of immigration, and the age composition of immigrants. These results suggests the importance of better understanding demographic characteristics of immigrants, specifically fertility and age characteristics, in order to interpret more effectively results of models of immigration, population growth.

Geographic Scale and Temporal Specification

Geographic scale is a critical conceptual and analytic dimension of contemporary perspectives on population and environment. The importance of considering the role of demographic processes in environmental change on regional and local scales of analysis is increasingly emphasized in literature on the relationship between economic development and the environment in less developed countries (see, for example, Arizpe, Stone, and Major 1994; Mink 1992; Ogata 1989:48; United Nations Secretariat 1991; Glaser 1980; Milliman 1992; Huguet 1992). Mink (1992:13), for example, calls for both spatial and temporal specification:

> The impact of population intervenes along three main dimensions: its scale in relation to the resource base, its rate of growth, and its redistribution across resources through migration. Population's impact on the environment is critical in some countries or regions within countries, but is less important in others. Moreover, the three dimensions will not be equally important for the environment in different places and points in time. Thus, assessments of population's impact on the environment, and the appropriateness of addressing such impact through direct population interventions, need to take local circumstances into account.

In reflecting on the study of environmental processes among island ecosystems, Glaser (1980:9) offers a very clear statement on the "limitations of global synthesis" in the study of population and the environment:

> The population/resource/environment situation differs from country to country and varies even from area to area within most countries, in particular the larger ones. The problems of assessing population/resource ratios, and of defining measures for their beneficial adjustment,

> must be tackled on a disaggregated and areal basis. In fact, there seems to be a need for almost every country to develop a population/resources environment model for its particular national situation for its major geographic subdivisions.

Bilsborrow (1992) argues for local and regional studies as opposed to cross-country analysis on the basis of principles of research design and the analytic goal to move beyond descriptive studies of covariation to conclusions concerning causal processes:

> While cross-country-level data have the appeal of generalizability, there are important reasons for focusing research efforts at the individual country level. One is the much greater possibility of controlling for other factors that influence demographic and environmental change, such as national resource endowment, climate and topography; soil quality; transportation linkages to markets and cities and availability of off-farm employment; access to family planning, health and education facilities; . . . and national and local government policies relating directly to the environment, such as restrictions against tree cutting, cost of logging concessions, and protection of parks and nature reserves. All of these factors, and undoubtedly others, may influence demographic processes, agricultural and land use change, and environmental degradation in rural areas.

A second reason for preferring within-country studies is that aggregate country-level data cannot relate well (differences in) natural resources trends to (differences in) demographic variables. If it were true that countries with faster rates of population growth appeared to be experiencing faster rates of forest loss, this would not necessarily mean that the two are related, particularly from the production or supply side, as per the focus in this paper. One would need to see if those areas *within* the country experiencing forest loss are also the areas experiencing population growth (in-migration). This can only be addressed at the country level . . . (Bilsborrow 1992:144-45)

Critical perspectives on the concept of carrying capacity further underscore the need to relate population and environmental processes on local and regional scales defined most appropriately by ecological analysis (see Bayliss-Smith 1980; Glaser 1980; Brookfield 1980; McCall 1985; Talbot 1986; Santos 1990:39-40,75-76; see also McConnell 1991). Carrying capacity is the size of population that can be supported by the resources of an ecological system. In human population, the concept must be understood to be dynamic, that is, open to change through technological and social factors. Hogan argues for the value of the concept of carrying capacity in order to relate demographic processes, resources, environmental trends, technological change, and patterns of production and consumption within specific regions:

> The value of the concept of carrying capacity is that it should direct our attention to specific ecosystems, exploited with specific technologies, to produce a specific standard of living. Here one may meaningfully relate population pressure to environmental degradation. (Hogan 1992:116)

Because carrying capacity is altered by technological and institutional change, the conceptual framework requires the specification of the temporal context for analysis. Hence, the short-term outcomes of migration for environmental change may be conceptualized quite differently for places and regions in comparisons to models with longer-term time horizons in which feedback between migration and social and technological change may be envisioned (cf. Simon 1990:188-92). A useful discussion of issues in the interpretation of the concept of carrying capacity is provided by Cater and Goodall (1992:312-13) who consider carrying capacity within specific destinations for tourists in Australia (see also Bayliss-Smith 1980; Huguet 1992:388). Because of the relatively short-term impact of increasingly large numbers of certain types of international migrants—tourists, business persons, students—in selected places in the United States, it may also be useful to explore the use of the concept of carrying capacity in relationship to the demographic notion of "person-years" of impact (K. Woodrow 199).

Meyer and Turner summarize these issues of scale concerning perspectives on population and the environment and also with relevance to conceptual models and research design: "Comparative assessments assume that if population is a key driver of environmental change, then the pressures of population (e.g. density) should

closely match the magnitude of various kinds of environmental change across regions and locales" (Meyer & Turner 1992:53).

Spatial, Sectoral, and Temporal Linkages

Finally, there is emerging emphasis on the significance of linkages across geographic scale and among regions that holds theoretical potential for informing conceptual models of the relationships between migration and environmental processes. The published results of interdisciplinary symposium, *The Earth As Transformed by Human Action* (see Turner, et al. 1990) address conceptual issues concerning interregional and intersectoral linkages by disentangling, both conceptually and empirically, the temporal and spatial patterns of the effects of human society on global and regional environmental processes at different scales. In this regard, Merchant (1990) provides critical insight to the characteristics and limitations of models of society-environment interactions. Again, however, the role of interregional and international population movement in processes of transformation in selected regions is not highlighted either in theory or application (see, for example, Ezcurra 1990).

Emphasis on linkages among regions and across geographic scales is often matched with attention to the dynamic dimensions of societal and environmental processes. For example, the University of Michigan Population-Environment Dynamics Project (Ness, Drake & Brechin 1993b) has emphasized the need for interdisciplinary study of human-environmental interaction and for theoretical refinement of general models of environmental impact (cf. Ehrlich & Ehrlich 1990). Transitional analysis, that is, interaction among processes of change, is underscored (cf. Lutz 1994:63; United Nations Secretariat 1991:58). Drake (1993) identifies several areas of global transition which characterize population-environmental dynamics including the demographic transition, epidemiological transition, and the urbanization transition. While trends in international labor and refugee movements are noticeably absent from this conceptualization, the framework is conducive to similar consideration of the prominence of international population movements in regional and global dynamics. The importance of determining the degree of synchrony in rate of change in transitions is particularly salient for the analysis of the role of international migration in social and environmental change in the United States (Drake 1993:334-48).

It is interesting to note that studies that place theoretical emphasis on the linkages between developed and developing countries and increasing international integration among economic sectors vary widely in the attention given to international migration. Some perspectives do not explicitly consider the role of international migration and population circulation as an important dimension of global and interregional economic relationships (see, for example, Bowlby & Mannion 1992:332; Contanza 1992; Cater & Goodall 1992:320; Sadik 1989:4,5; cf. Berreby 1994:49). Other perspectives on economic development in developing countries emphasize the importance of international and interregional labor migration in economic change in both send-ing and receiving societies and in trends toward increasing global economic integration and interconnectedness (see, for example, Massey, et al. 1987, 1993; Massey 1988; Castles & Miller 1993; Bailey & Ellis 1993; see also Simon 1990:274-76).

Perspectives on the role of the United States in global environmental protection place emphasis on the significance of the United States in global economic integration, international trade, and the potential for sustainable development in southern regions (Ridker 1975; Keyfitz 1991; Cooper 1991; Sadik 1989:4,5). The relationship between U.S. foreign policy and migration pressures in developing countries has also received increasing analytic attention (see, for example, Tucker, Keely & Wrigley 1990; Loescher & Scanlan 1986; Teitelbaum & Weiner, forthcoming). Absent from these discussions, for the most part, is explicit conceptualization of the role of U.S. immigration policy as an agent of global and regional environmental change. Ehrlich and Ehrlich (1992:331) do relate issues of brain drain to the acquisition by immigrants of patterns of consumption associated with U.S. lifestyles: ". . . even though immigration to the United States does not produce a net increment to the global population, it does produce a net increment in total environmental impact."

There is a need for additional thinking about the role of international migration and, specifically, immigration to the United States on patterns of environmental change in both sending and receiving communities. The role of environmental degradation in serving as a stimulus to out-migration from agricultural areas, rapid urbanization in developing countries, and international migration is receiving increasing attention (see for example, Myers 1991; M. Schwartz, 199). The role of U.S. immigration policy and patterns in these processes is an area of needed theoretical development.

Implications for Theoretical Research on U.S. Immigration and the Environment

This wide-ranging discussion of perspectives on population, migration, and the environment suggests several areas of needed scholarship, the most fundamental of which is the need to revise models of environmental change and impact to incorporate more effectively concepts of migration. Of particular relevance for the United States, moreover, is the specification of effects for different types of international population movements (permanent resettlement, refugee migration, temporary labor migration, and tourism) within theories of environmental impact.

Recommendations for Theoretical Research

1. General models of environmental change and impact should be reformulated to specify the role of migration and, specifically, international migration in processes of population growth, consumption and production, and technological change.

   a. Hypotheses concerning the short- and long-run effects of migration processes for these relationships and environmental outcomes should also be derived.

   b. The reformulation of theoretical models should also recognize the importance of geographic scale for both scientific analysis and policy and program development.

   c. Attention should be given to the dynamic relationships among sources of population growth and social, economic, and technological change.

   d. The relevance of intersectoral linkages, illustrated, for example, in the global division of labor in manufacturing, for environmental process at different scales of analysis should be investigated.

2. Specific theoretical research should be devoted to conceptualizing the role of international migration as an agent of change in environmental-related processes: technological change, and the promotion of shifting patterns of consumption and production within both countries of origin and destination. As emphasized above, conceptual models should consider these relationships specific to major types of international migration and mobility.

a. The environmental consequences of immigration should be specified within economic sectors, as well as among geographic areas; for example, the environmental implications of the relationship between international migration and changes in agricultural practices in countries of origin and countries of destination should be conceptualized, as well as the environmental consequences of relationships between labor migration associated with the spatial and technological reorganization of manufacturing.

3. Theoretical research should be undertaken to conceptualize immigration as a component of population dynamics at different scales of geographic analysis.

a. A critical assessment of approaches to measuring sources of population growth in relationship to different models of environmental change should be initiated.

4. Theoretical attention is needed concerning the concepts of urban efficiency and scale in relationship to environmental quality, available resources, and patterns of urban and metropolitan spatial growth. These concepts should be related to sources of population growth as outlined in previous recommendations.

EMPIRICAL RESEARCH CONCERNING MIGRATION AND ENVIRONMENTAL PROCESSES AND CHANGE

Introduction

Deep analytic traditions exist in western social science for conceptualizing and measuring the consequences of international migration for national society, economy, polity, and for interregional migration for local communities. Scholarly interest in the environmental consequences of immigration, certainly, in the case of the United States, has a much more shallow history, originating in the late 1960s with environmental concern over national population growth and the role of annual alien immigration in paths to population stabilization (see Coale 1972; U.S. Commission on Population Growth and the American Future 1972; see also Keely & Kraly 1978). Complementary to these concerns is demographic interest in the historical contribution of immigration to national population growth (see Gibson 1975; Keely 1974).

As described above, there is current interest in the environmental implications of immigration for regions, states, and local communities in the United States. Most research, however, tends to focus either on population growth and trends in immigration, i.e., the independent variables, or on environmental processes and problems, the dependent variables. There exists very little direct causal analysis of relationships among population, immigration, and environment in the United States. Sparse empirical attention has been given, for example, to the unique effect of immigration in studies of subnational population dynamics. Similarly, the role of immigration status, nativity, and ethnicity in analyses of consumption and production remains to be fully specified and empirically evaluated. For example, comparison of patterns of energy consumption, commuting, land use patterns, and water conservation practices between foreign and native born, among immigrant cohorts and generations, and among groups of immigrants would add to discussions of the environmental consequences of immigration. Similarly, analyses of the significance of immigration status relative to social and economic characteristics for levels and patterns of consumption should be undertaken.

Because of the relative absence of empirical studies concerning the environmental consequences of U.S. immigration and, generally, international migration to and from the United States, we have looked broadly at the research literature for empirical studies that are relevant for informing the development of a national research agenda. This review has taken us to scientific areas that at first glance do not appear highly relevant for framing studies on U.S. immigration and the environment. The selected areas of research do, however, illustrate salient issues in conceptualization, research design and analysis, and interpretation of findings.

It should also be acknowledged that comparative research on the implications of trends in international migration and mobility has not given prominent attention to the environmental consequences of population movements in comparison to issues concerning economic and development processes, social integration and immigrant adjustment, and foreign relations (see, for example, Vernez 1990; de la Garza, Rodriguez & Pachon 1990; Massey, et al. 1987; Appleyard 1992; Tucker, Keely & Wrigley 1990; Kritz, Lim & Zlotnik 1992; Kritz & Keely 1983; Kubat 1993; Elliott 1989; Zolberg, Suhrke & Aguayo 1989). There is empirical research, most often field studies, however, concerning the converse relationship, that is, the contribution of environmental degradation and crisis to patterns of migration. Studies of

environmental refugees acknowledge the economic and political dimensions of poverty in tandem with population growth in the erosion of local and regional environmental conditions that then result in out-migration. Environmental refugee movements thus emerge from changes in land use and land degradation associated with shifts in agricultural organization, such as farm ownership and land tenure systems, and such patterns of production, as single versus multiple cropping (see, for example, Catanese 1990-91; Tamondong-Helin & Helin 1990-91; Jacobsen 1988; Purcell 1991; Appleyard 1992; Sadik 1989; Talbot 1986; World Resources Institute 1994-95; Zolberg, Suhrke & Aguayo 1989:103-25). Studies of the relationship between natural disasters and migration and population displacement similarly reveal the role of social and economic factors in mediating the differential effects of natural calamities for local and regional populations and communities (see, for example, Clarke et. al. 1989). Research has also addressed the role of environmental factors such as groundwater use in population dynamics and community sustainability (see White 1994).

Research on Regional and Local Population-Environmental Dynamics

Commenting on research concerning economic development in rural areas of developing societies, the United Nations Secretariat (1991:65) makes an important observation about the relationship between population processes and land degradation, relevant for empirical research concerning population, migration, and the environment:

> While the outlines of this environmentally destructive interaction between growing populations and land degradation are clear, the magnitude of the problems, their geographical distribution and their causes remain unclear. These ambiguities must be investigated analytically if Governments are to address these environmental problems in an effective way.

There are, however, empirical studies of the interrelationships among population, migration and environmental processes that transcend the analytic problems identified by the UN above. For example, Arizpe, Stone, and Major (1994) have sought to synthesize important empirical research on population and environment in developing socieites. Their critical analysis of existing research serves to inform the development of conceptual models of population, migration, and the environment, as well as appropriate research design and data requirements (see also Palloni 1994). Among their conclusions is the need for continued research on the connections between population and environmental processes within local and regional contexts (Arizpe, Stone & Major 1994:8-9; see also Lutz 1994:63).

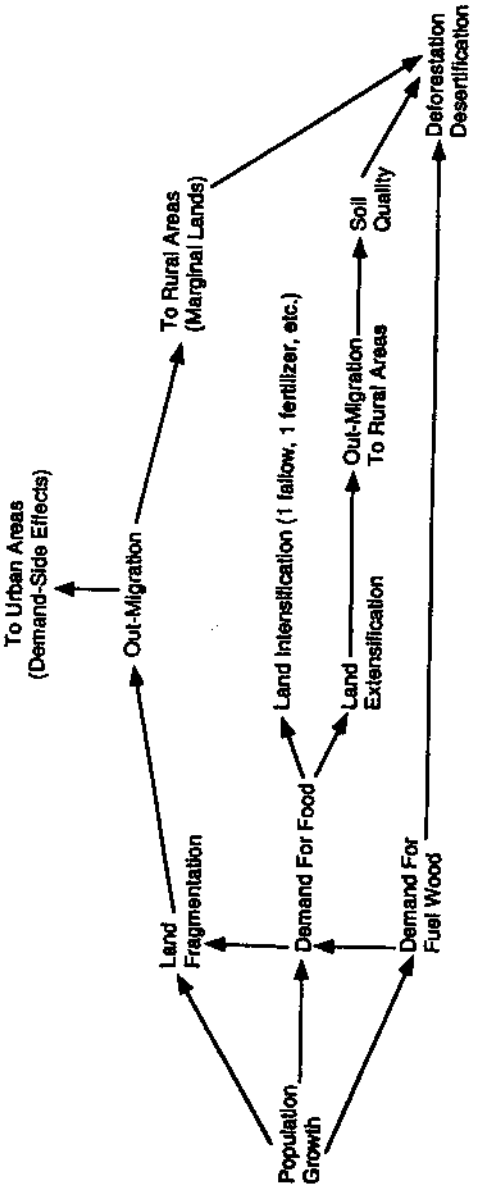
For example, in a series of papers, Bilsborrow and his colleagues have explicitly established goals to conceptualize and measure relationships between demographic processes, notably migration, environmental outcomes, and agricultural practices in particular (see Bilsborrow & Geores 1994; Bilsborrow 1992; Bilsborrow & Stupp 1989; Bilsbor-row & DeLargy 1991). Bilsborrow's conceptual model of land extensification in developing societies, shown in **Figure 1**, specifies the nature of the relationships among population growth and trends in land and resource use, change in land use and agricultural practices, migration, and environmental degradation. While the model might be criticized for the omission of other factors influencing land use change, such as national agricultural and food policies and urban-directed development programs, the empirical research to test the model is significant in measuring the structural and behavioral linkages among social processes and environmental change and, as a result, providing a basis for causal explanation and theoretical development.

Bilsborrow (1992:145-46) also emphasizes the necessity of measuring changes in these processes over time and the value of survey methodology to identify micro-level relationships:

> A number of other scholarly studies have used individual country data on changes over time, sub-national data, to study relevant population-migration-environment linkages, but few identified specific mechanisms by which population factors cause environmental change. . . . I believe we came close to doing this in a study of Guatemala . . . linking rural population growth to land fragmentation and out-migration, but the subsequent link from household to deforestation

Figure 1.

CONCEPTUAL FRAMEWORK OF RELATIONSHIPS BETWEEN POPULATION GROWTH, MIGRATION AND THE RURAL ENVIORNMENT



Source: Adapted from Bilsborrow 1992:129.

is more circumstantial. For this reason I am proposing a household survey in areas of both in-migration and out-migration in rural Ecuador to examine this possible linkage. This is necessary to determine where the migrants come from and why, how they acquire land, and what they are doing with it, including past and present forest-clearing practices.

Interestingly, in a study of the environmental consequences of rural out-migration in Nepal, Thapa (1993) implements several of these analytic recommendations. Thapa utilizes a household survey to measure directly the relationships between household characteristics, agricultural practices, migration patterns, patterns of consumption and remittances, and watershed management practices. The augmentation of household income through remittances did not promote watershed conservation that were devoted primarily to meeting basic household needs; instead, emigration in the study areas was found to be associated with watershed degradation resulting from insufficient labor available for land management and the reliance on pooled labor and economic resources.

Similar analytic strengths are evident in research by Young (1985) and Talbot (1986) that considers migration processes in the form of settlement schemes in Africa. Young studies the environmental consequences of refugee settlement programs in Somalia by collecting detailed data on the agricultural and domestic practices of refugee households in relationship to measurable environmental outcomes: changes in grazing, vegetation, erosion, and soil quality; trends in irrigation and salinization; and loss of forest resources. Included in the analysis is information on environmental conditions in the selected regions prior to the refugee agricultural program, as well as documentation of trends in agricultural practices and environmental outcomes. In a similar fashion, Talbot (1986) studies the social and environmental effects of population growth in rangeland areas in east Africa. Changes in population size among the Maasai are related to resources, primarily livestock, necessary to support traditional ways of life. Balance between demographic and social structure and natural resources has been disrupted in large part by forces external to Maasai society and include population growth among agricultural groups, development programs concerning settlement of pastoralists, and environmental degradation associated with agricultural change.

A similar framework and approach is followed by McCall (1985) in his detailed analysis of the environmental effects of villagization programs in Tanzania. Like

Bilsborrow, McCall raises important analytic issues concerning the empirical basis for interpreting relationships between such social demographic processes as resettlement and environmental degradation in this region of Africa. His conclusions (1985:139) are provocative: ". . . villages are here to stay and there can be no solution which involves eliminating them. The [environmental] impacts emphasized have been mainly the negative ones; there are of course positive effects on services, information and accessibility. A full evaluation would also have to address the methodological problem of comparing 'with and without'—what direction would rural development have taken in the past decade without villagization?"

Research on Environmental Outcomes

Environmental research that focuses on direct measurement of environmental processes and quality is often characterized by indirect or cursory measurement of population and social processes that are often presented initially as causes of environmental change (see Keough & Quinn 1991:539-41). For example, research in Japan (Bower & Takao 1993) has documented patterns of land reclamation in Tokyo Bay and the implications for coastal resources and environmental quality. Causes of land use change include trends in urbanization and migration, industrialization, dredging technology, and political organization among fishing cooperatives. The analytic focus of the research, however, concerns the analysis of environmental outcomes, not the specification and measurement of the relationships among causal influences or between social and demographic causes and environmental effects. In a similar fashion, Tamura (1993) hypothesizes about the effects of urbanization, economic development, and innovations in earthwork technology on residential development in hill regions in Japan but measures environmental processes not causal relationships.

Environmental research concerning coastal zones and marine systems almost uniformly identifies population growth, migration, and temporary population movements (tourism) as ultimate causes of environmental degradation. In their study of fresh and waster water discharge along the California coast, Griggs and McCrory (1975) identify population growth as the fundamental cause of pollution in nearshore marine environments. The empirical substance of the study, however, is the analysis of the spatial variation in volume and composition of

nearshore water discharge rather than an analysis of causal effects of demographic and economic factors. Linden (1990) discusses the complex interactions among social, political, economic, and demographic factors in relationship to environmental processes in tropical coastal zones, but presents detailed documentation only for the environmental problems observed in specific coastal regions. Using a more explicit model of spatial covariation, Saliba (1990) similarly emphasizes the impact of tourism, industrial activity, and agricultural practices for land use change and environmental problems in Mediterranean coastal areas.

Finally, an excellent collection of papers by marine scientists concerning human impacts on the seafloor emphasizes patterns of global and regional social, economic and demographic change as potential causes of environmental degradation of the deep ocean floor (see Hsu & Theide 1992). Aggregate world population growth, trends in migration to coastal areas, and patterns of consumption and economic activity are identified as ultimate causes of marine environmental change (see Milliman 1992; Bunt 1992: 229; Vadus, Bregman & Takahashi 1992). For example, in a summary group statement, Burnett (1992:245) reports:

> Pressures caused by exponential population growth over the past several decades have resulted in two great needs which will affect human interaction with the deep ocean: (a) demands for additional resources; and (b) localities for waste disposal. Although large-scale deep ocean mining and solid waste disposal are not presently occurring, depletion of land resources and environmental damage on land require that we give consideration to future use of the seafloor as a course of minerals and as a repository for anthropogenic wastes.

The focus of the analysis, however, is the documentation of available data concerning the characteristics and patterns of change in deep ocean environments and the delineation of information needs for monitoring change.

Urbanization and Environmental Issues

There is extensive research on the relationship between patterns of urban population growth and urban and metropolitan

environmental problems in both developed and developing nations. In not all studies of urbanization, however, is the role of urbanward migration considered separately from natural increase. Speare and White (1992:91) examine the concept of optimum city size given environmental criteria and specify the nature of the relationship between city size and environmental quality by identifying the effect of two concepts, population density and homogeneity:

> Smaller cities have two advantages in dealing with the environment. First, because of smaller size and typically lower density, they have less concentration of pollutants to deal with, other things being equal. Second, because they have a smaller and often more homogeneous population, they may have an easier time mobilizing support for programs to regulate and reduce pollution.

The role of migration is considered only indirectly through concepts of urban population growth and racial and ethnic composition. Moreover, while the nature, extent, and trends in urban environmental problems are often documented, the causal relationships between population growth and environmental outcome are not empirically tested and established (see Milne 1988; Sarre & Smith 1991; Huguet 1992:388-90).

Increasing research is being conducted concerning the consequences of immigration for metropolitan and regional growth patterns in the United States (see Frey 1994; McHugh 1994; Kraly & Hildebrandt 1993; cf. Frey & Speare 1992). Scientific assessment of the effects of immigration for cities and regions has focused on specific infrastructural effects and relationships (see Clarke, et al. 1994; Fix & Passel 1994; Vernez 1993). Studies that seek to address environmental consequences of immigration for urban areas, however, are often plagued with the analytical problems described above: patterns of population growth and immigration are observed to covary with environmental outcomes, while causal relationships are not directly tested. To illustrate, in a study of the sources and distribution of population growth in California, Goodenough (1992:124) states: "[i]n the last decade one-quarter of the US population growth has occurred in the state, generating problems in school provision, transportation, air and water quality and agricultural land conversion." The author interprets shifts in commuting patterns as a response of native residents to intrametropolitan pressures and problems. No direct data on residential choice or commuting behavior, however, are presented.

Research on Immigration and the Environment in Australia

A final body of scholarship that is directly relevant for framing research questions concerning U.S. immigration and the environment derives from Australia. Debates strikingly similar to those emerging in the United States (see Jones 1992:362) circle around the degree to which immigration to Australia should be manipulated in order to achieve national environmental goals and maintain natural capital, relative to such other sources of environmental impact as internal population movements, temporary and seasonal international migration, market forces, patterns of consumption, technological change, etc. Recent government response to increasing public concern about environmental issues in Australia has emerged in the form of goals concerning "ecologically sustainable development." Moreover, according to the National Population Council (1991:x), a group appointed by the Prime Minister to assess the implications of population growth, immigration is considered the essential component in the development of a national population policy for Australia. Correspondingly, government sponsored research has been initiated to assess the effect of population growth, hence, levels of immigration, on the "ecological integrity" of Australia, its sparsely populated regions (Clarke, et al. 1990) and metropolitan areas (Murphy, et al. 1990; see also National Population Council 1991; Nieuwenhuysen 1992).

Fincher (1991) has synthesized these and other research findings concerning the relationships among immigration, population, and environmental processes and issues in Australia. Consistent with the discussion above, she underscores conceptual, analytic, and data difficulties inherent in the available empirical research concerning these relationships. For example, research on optimum city size struggles with the identification of justifiable criteria for determining thresholds in population associated with environmental damage. On the one hand, immigration to Australia is clearly associated with the centralization of the population in metropolitan areas. On the other, the hypothesis that immigration results in increased suburbanization and, hence, decentralization of population within metropolitan areas has yet to be effectively tested through either survey research concerning residential choice or analysis of trends in the supply of and demand for housing and service infrastructure

throughout metropolitan areas (see Murphy, et al. 1990). In this regard, Fincher (1991:33) observes that "[i]f refugees, for example, require public housing, then the public and private rental market nearby may suffer. If wealthier business migrants bid up housing prices in certain localities others may be not longer able to afford housing there. Indeed the degree to which immigrants' arrival 'pushes' others to the urban fringe by bidding up house prices further in, or by taking up scarce public and private rental housing, is unclear." Hence, both patterns of immigrant settlement and the degree of variation in characteristics of immigrant groups also prompts Fincher to note the importance of conducting local and regional analysis of the impacts of immigration on urban infrastructure in Australia cities.

The available research on energy and water consumption in Australian cities has yet to measure directly the effects of urban population growth and immigration. Fincher (1991) identifies the multiple causes of air pollution and increases in the demand for water. For example, the lack of clear evidence on the connection between immigration and residential relocation to the fringes of metropolitan areas erodes conclusions about the general relationship between immigration and automobile energy use (Murphy, et al. 1990:163).

The role of immigration in environmental degradation in nonmetropolitan environments in Australia has been considered by Clarke, et al. (1990) and Flannery (1992) among others (see also Blaikie & Brookfield 1987). Clarke, et al. (1990) place the analysis of environmental issues in both agricultural practices and ecologically fragile environments in Australia, first, in historical context and, second, within a framework of international and regional economic relationships. For example, in assessing the relation of Australian population growth to agricultural sustainability, it is important to reveal the connection between agricultural practices and production for export markets. The relationships between international trade and stock of natural resources must also be considered. Similarly, these issues are also relevant for the analysis of the implications of tourist migration to remote and/or fragile environments throughout Australia.

> Whether those tourists are Australian-born or not, or whether they are attracted here because they are friends of recent immigrants, seems rather a trivial point. The importance of wilderness areas to our growing tourist industry, a further use of

> our resources for economic growth, is undeniable. . . . Curtailing the immigrant intake of permanent settlers would not stop this. But there is cause to examine the impact on these sites of the growing number tourists and temporary visitors. (Fincher 1991:44)

Coming somewhat full circle, Fincher's perspectives also reveal the conceptual and analytic importance of developing more refined specification of demographic sources of environmental impact.

Implications for Empirical Research on the Relationship between U.S. Immigration and the Environment

As shown here, very little direct research has been initiated concerning the relationships between U.S. immigration and the environment, a situation that is not uncommon in other major immigrant receiving countries (cf. Canada Employment and Immigration Advisory Council 1991; National Population Council 1991). Perspectives on U.S. immigration and environmental processes remain largely on the conceptual, if not rhetorical, level of analysis, with results of demographic models translated into environmental outcomes concerning resources availability and environmental quality (see, for example, Pimental & Pimental 1992; cf. Parkes & Dennis 1993). In this regard, population-environmental research in the United States lacks precise or explicit specification of relationships between demographic processes and environmental change.

The general observation concerning the status of empirical research on U.S. immigration and the environment is the need for more of it. There is critical need for the initiation of well-designed studies that will yield both descriptive information concerning trends and patterns of demographic and environmental processes in U.S. regions, as well as for causal analyses of the relationships between migration and environmental change. Given this starting point, the recommendations for empirical research for the United States are relatively basic, unlike recommendations for research developed by Fincher for Australia (1991:57-50). In contrast, the suggestions presented below reflect fundamental needs for baseline data on trends and patterns and causal analysis to test hypotheses deriving from conceptual models of immigration-environment relationships. In important ways, several of

the recommendations for research are connected to issues concerning both conceptualization and data availability and quality discussed in sections above and below, respectively.

Recommendations for Empirical Research

1. Research should be undertaken to synthesize what is known about the components of population growth and change on the regional, state, metropolitan, and local levels in the United States.

a. Analytic attention should be given to trends in each source of migration to and from geographic areas, including permanent resident aliens, temporary visitors (including foreign students and temporary workers), and refugees.

b. Patterns of secondary or internal migration of immigrants should be documented and distinguished from patterns of initial settlement among immigrants.

c. The process of temporary international movements and mobility, such as international tourism and temporary workers, should be measured and described for regions, states, and metropolitan and local areas in the United States.

2. Research should be initiated to document what is known about trends and changes in environmental processes, resources, and quality for regions, states, and metropolitan and local areas in the United States. Environmental data should also be organized in relation to such ecological systems as marine and coastal environments, aquifer basins, as well as other relevant units, for example, national parks and wilderness areas.

3. Research to measure causal relationships between immigration processes and selected environmental outcomes should be initiated for regions and local areas.

a. Macro-level analyses that measure the relationship over time between each source of population change and regional and local environmental indicators should be conducted; control for other exogenous sources of environmental change should be considered carefully in such research.

b. Micro-level studies of patterns of consumption and use of environmental resources should be initiated to provide estimates at the national and subnational levels.

c. Studies of environmental behavior should relate the effects of immigrant characteristics (country of birth, length of residence, patterns of internal migration) to the effect of social demographic factors (age, gender, household composition, education, occupation, etc.).

4. The effect of immigration trends in urban environmental quality and resources should be measured, again, within the context of other sources of environmental change and given a dynamic analytic framework. Case studies of environmental change within specific urban and metropolitan areas should be undertaken.

a. Analysis of the role of immigration in the geographic expansion of U.S. metropolitan areas should be initiated.

b. Research on the effect on immigration on urban housing markets and patterns of commuting should be initiated for specific cities and metropolitan areas.

METHODOLOGIES FOR ASSESSING THE ENVIRONMENTAL CONSEQUENCES OF U.S. IMMIGRATION

Introduction

The emerging wisdom from studies and perspectives on population-environment dynamics includes recommendations to pursue research, assessment, and monitoring of interrelationships on local and regional scales (for example, National Research Council 1992; Fincher 1991; Turner, et al. 1990; National Population Council 1991; cf. Linden 1990:10; Bunt 1992:229) and with comparative methods and cooperative synthesis of findings (Ness, Brechin & Drake 1993c; Harf & Trout 1986). These analytical visions of the necessity for regional and local analysis and comparison of effects are particularly consistent with what has been learned from research efforts to assess the economic effects of immigration on U.S. labor markets and communities.

We have initially considered two analytic frameworks that have been developed to study dimensions of environmental change: environmental impact assessment (see Westman 1985; Mather & Sdasyuk 1991; Clark & Herrington 1988; Black 1981) and population-environment monitoring systems (see Westman 1985; Ness, Brechin & Drake 1993b). Environmental impact assessment most often attempts to forecast the impacts of development projects or structural or engineering initiatives, generally, new activities within a geographic area (see, for example, Newson 1992 :261-70; cf. Ofori-Cudjoe 1990). Monitoring systems represent ongoing social and environmental accounting frameworks for the collection and analysis of data over time for specific geographic areas.

Environmental Impact Assessment

Lein (1991-92:168) describes environmental impact assessment [EIA] as "the principal means of understanding human impacts on the environment within a structured decision-making framework." The formal adoption of EIA as an approach to anticipating environment change came in 1970 with the requirement in the National Environmental Protection Act for federal agencies to formulate environmental impact statements [EIS] for proposed activities (see Rosenbaum 1991:14). The analytic objective of the EIA process is the provision of objective, typically quantifiable, information for policy-makers and program administrators concerning the range of environmental consequences of some proposed source of change for a region or place. The results of the process thus contribute to the identification of an "informed trade off among conflicting aspects of a proposed activity" (Lein 1991-92:168). Environmental assessment is thus conducted for a specific place, time and proposed event. The emphasis on short-term environmental effects is, according to Lein, a disadvantage of the methodology for long range environmental planning and the avoidance of irreversible environmental damage.

The steps followed within the EIA process are often described schematically as a decisionmaking tree or flow chart. To illustrate, **Figures 2a** schematically shows the EIA process for the United States, and **Figure 2b** shows the process as organized by the Scientific Committee on Antarctic Research. The actual process of assessment, that is, measurement of environmental outcomes of a proposed program or activity, is usually not specified but represented as an activity box with the

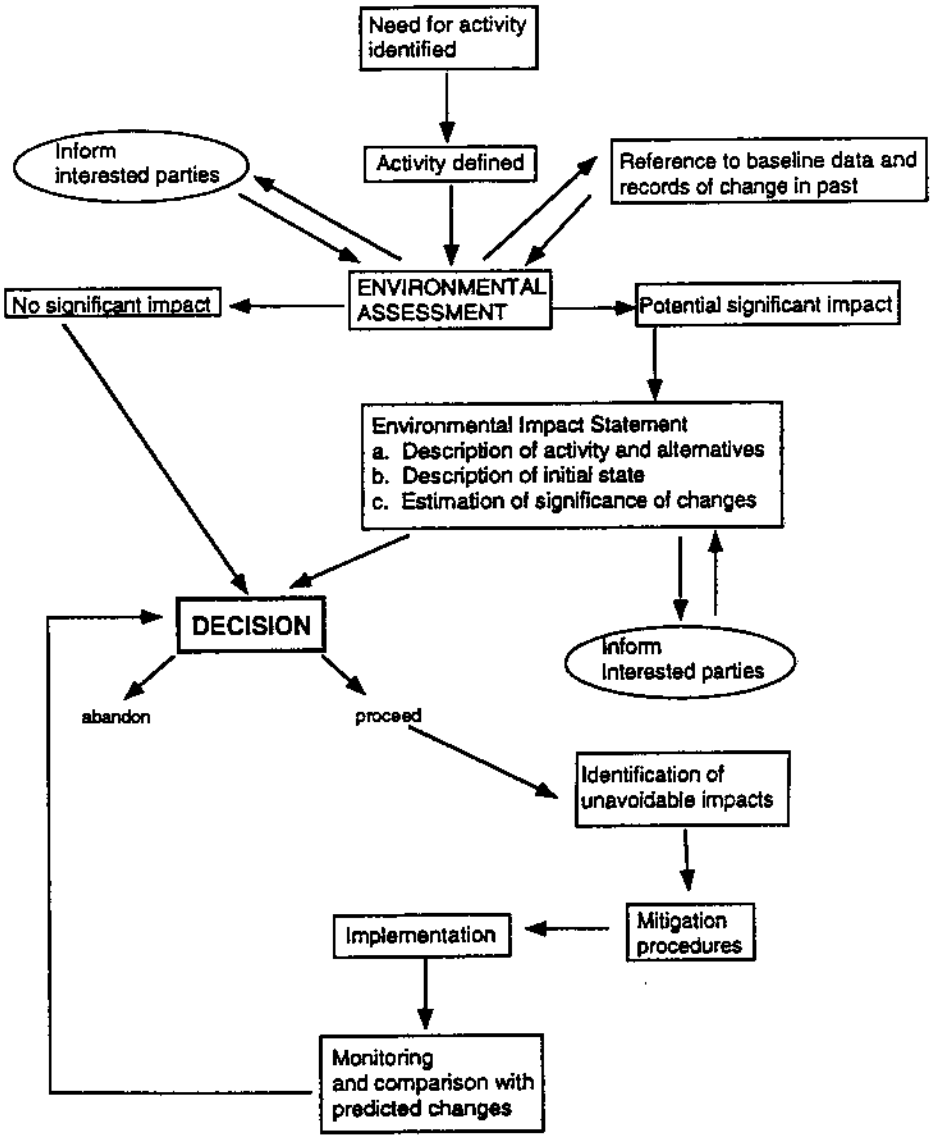
THE ENVIRONMENTAL IMPACT ASSESSMENT [EIA] PROCESS AS ENVISAGED BY SCAR



Source: Adapted from Bonner 1986:86

flow chart. Discussions of environmental impact assessment indicate only in broad strokes the methodological approach. Newson (1992 :268) describes the tasks of assessment as including:

> Identification methods—to assist in identifying the project alternatives, project characteristics and environmental parameters to be investigated in assessment
>
> Data assembly methods—to assist in describing the characteristics of the development and of the environment that may be affected. Predictive methods—to predict the magnitude of the impacts which the deveopment is likely to have on the environment
>
> Evaluation methods—to assess the significance of the impacts which the development will have on the environment
>
> Communication methods—to assist in consultation and public participation, and in expressing the findings of the study in a form suitable for decision-making purposes
>
> Management methods—to assist in managing the scoping of the study, the preparation of the impact study, the efficient conduct of the consultation process, etc.
>
> Decision-making method—to assist decision-makers in assessing and understanding the significance of environmental impacts relative to other factors relevant to a decision on the proposed development

Similarly, Bonner (1989:86-87) identifies within the process of EIA: first, specification of the proposed program or activity as well as alternatives; second, provision of baseline environmental data on the local region or site and an estimate of changes in those measures in the absence of the proposed activity; estimates of the "nature, extent, duration and intensity" of the predicted environmental outcomes; and evaluation of the significance of the predicted impacts and possible approaches to mitigate the effects.

Inherent in these methodologies of environmental assessment are theoretical models of the causes and effects of environmental processes. Predictions about the impact of human activities on the environment of a defined region require not only specification of significant causes of environmental impact, change, or disruption, but also of the nature, that

is, form and direction, of the relationships between the causes and outcomes. Newson cautions, moreover, of the problems in predicting environmental change without an appreciation of the full spectrum of sources of change. Hence, answering the basic questions of environmental assessment—"What will be the direction of future change? By how much? How certain are we?" (Newson 1992 :264) requires an assessment analysis that is embedded in a dynamic and comprehensive model encompassing all the important sources of environmental change for the study area. This, according to Newson, is the process of 'scoping' (Newson 1992 :264,268; see also McNabb 1989:109; Colthern 1993b:6).

The results of EIA are often summarized in the form of a matrix in which scores are assigned to each combination of impact and outcome. McNabb (1989), among others, has been critical of the tendency in this approach to simplify complex, essentially multivariate relationships between social processes and environmental outcomes. What is as critical is the degree to which the approach subdues the influence of both theory and method. For example, in an *ex post facto* environmental assessment of an electric power plant Ofori-Cudjoe (1990) presents the EIA matrix relating each of the components of the plant construction and operation to seventeen environmental outcomes, including impacts on the physical, biological, and social environments. The matrix is shown in **Figure 3**. The methods of determining the scores for each cell of the matrix, that is, the level and direction of the impact, rely on observation, documentation, and interviews with members of the resettled communities: "[t]he only positive impacts on the physical environment are on agricultural land-use and surface water quantity. The people expressed a lot of misgivings during our fieldwork. Their oil palm plantations stood in danger of destruction without sufficient compensation" (Ofori-Cudjoe 1990:124). The underlying conceptual relationships, however, remain implicit in the assessment process.

Critical perspectives on EIA underscore the importance of studying environmental change within a multivariate framework in which all exogenous influences on environmental outcomes are documented and comparatively evaluated. The observation of Preston (1993:600) is relevant: "Even if links can be established between demographic and environmental change, there remains the difficult task of evaluating the costs of environmental change relative to other things that humans value." The approach inherently assumes, moreover, that the counterfactual can be known; that is, that the causes and

consequences of environmental change are sufficiently well understood to be able to predict outcomes resulting from both the presence, as well as the absence, of the causal influence. Using the issue at hand and also following Simon's example (1990:190), one might ask whether enough is known about the role of immigration in technological and environmental change to conclude what the urban environment would have been like in the absence of immigration to the United States during the nineteenth century.

Population-Environment Monitoring Systems

The process of EIA involves not only predictive and hence causal analysis, but also monitoring and auditing of the outcomes of the program or activity through some future point in time (Newson 1992 :264). Population-environment monitoring systems [PEMS] are useful in providing an empirical foundation for evaluation of existing policies (Zinn, Brechin & Ness 1993) and baseline data for identifying subsequent environmental impacts. If the approaches to monitoring are standardized across administrative units, data for smaller geographic units can be aggregated and, thus, results of PEMS can support analysis of regional dimensions of national policies. This characteristic of PEMS is critically salient for purposes of U.S. immigration policy evaluation and recalls the effort by Clark et. al. (1994) to apply common methods of measurement among states in their study of the fiscal impacts of U.S. immigration. Further, population-environment monitoring assumes the collection of logitudinal data concerning interrelationships among social demographic and environmental processes. Newson's emphasis on the importance of identifying all significant causal influences is also salient for the PEMS approach. The analysis of observed trends in population and environment processes must be embedded within the context of social, economic, political, environmental change occurring on each relevant level of analysis: local, regional, national, and global.

Relevance of Methodologies for Analysis of Immigration and Environment

There are challenges to interpreting the predictive results of environmental impact assessment or even the results of environ-

mental monitoring. In reference to EIA statements, Westman (1985:9) states, "[f]or an accurate prediction of cumulative impacts to be made, impact analysts must be able to refer to some plan for the future development of the region. The plans in turn usually derive from a set of policies for regional development and national goals, and values. To speak to the combined effects of independent proposals for a region, impact assessment is dependent on regional planning." The implication is the need for clearly articulated goals and priorities concerning immigration and the environment for the geographic area. It is important to acknowledge in this regard the potential for conflict between national (and international) goals concerning immigration, for example, family reunification, refugee resettlement, and local and regional concerns, which are increasingly characterized by NIMBY ["not in my backyard"] frames of reference (cf. Castles & Miller 1994).

Turning to the application of the approach to the analysis of the environmental consequences of U.S. immigration, environmental impact assessment may serve as an appropriate approach if the analytic goal is to determine or predict the environmental effects of changes in the levels and patterns of immigration to an area within the country. In this case, the EIA methodology may be useful in assessing various immigration policy options that might include changes in overall levels of annual alien immigration to the United States, as well as changes in the structure of immigrant admissions in terms of individual and family characteristics. Such analysis would also include models of internal or secondary migration among immigrants and generally consider the consequences of immigration in a longitudinal perspective for the nation, region, and local areas. Comparison of different assumptions about both patterns of geographic settlement and secondary migration among immigrant groups may be particularly relevant for efforts to balance federal immigration goals with economic and environmental goals and programs for states and metropolitan and local areas.

In conducting such analyses of immigration and environmental change, however, the most critical issue in exploring the use of EIA or PEMS is the degree to which the environmental impact study or monitoring system incorporates all factors (social, economic, institutional, etc.) in relationship to population processes (components of growth, rates of growth, etc.) and demographic characteristics (age, gender, education, income, etc.) that are hypothesized to have environmental impact, using the concept of Ness, Drake, and Brechin, the population-environment

dynamic. In the general IPAT model, patterns of consumption [A] and technology [T] may be conceptualized as mediating the effects of demographic characteristics and processes on the environment (cf. Demeny 1991:410; Arizpe, Stone & Major 1994:8; Ehrlich & Ehrlich 1990). Methods of assessing or monitoring environmental change require, however, explicit specification of the nature of the relationships between demographic processes and behaviors, patterns of consumption and production, sources of technological and social change, and environmental outcomes. Moreover, as discussed above, emerging perspectives on global and regional dynamics have focused more critically on reexamining the institutional realm of mediating factors (see Arizpe, Stone & Major 1994; Ness, Brechin & Drake 1993b; Merchant 1990; Simon 1990; Espenshade 1991; Jones 1992), noting the variation in effects at different scales of analysis (see Meyer & Turner 1992:53-54).

As discussed above, these requirements for analysis assume a strong base of knowledge about population, migration and environment dynamics. Another way of expressing these analytic problems is the recognition of the limitations of knowledge about the counterfactual: What would have been the status of an area's environment in the absence of immigration? What will be the patterns of environmental change associated with different levels and patterns of immigration? Is there sufficient empirical evidence and accumulated knowledge to model or project these relationships in order to predict environmental outcomes associated with different immigration policies?

These issues provide an imperative for analytic approaches seeking to address the relationships among population, migration, and environmental change to incorporate—measure—the significant factors that determine the environmental impact of immigration to the nation or locale, beyond the direct effects of increasing population size. From the emerging literature we can quickly identify such factors as patterns of resource consumption, technological innovation and production of knowledge, conservation behaviors, land use patterns, etc. Further exploratory research may be required, however, to complete the model of causal factors, that is, behaviors and institutional arrangements with environmental impacts.

The challenge is thus to develop behavioral and structural models and incorporate them in methodological approaches to studying environmental change. In this regard, survey methodology has been shown above to hold particular promise for revealing the relationships among population, migration, and the environment. Macro-level analyses of these relationships will provide relevant results if

research designs are dynamic, longitudinal, and encompass or control for the effects for other exogenous sources of environmental change. Finally, the relevance of any EIA, monitoring system, or other more appropriate research design for determining the effect of U.S. immigration on the environment will rest, finally, in the degree to which *national, state,* and *local* data collection systems or ongoing surveys can support multivariate analysis of complex dimensions—demographic, economic, institutional, behavioral—of environmental outcomes.

Recommendations for Research on Methodologies

1. A review of research methodologies inherent in environmental impact assessments and population-environment monitoring systems should be conducted.

   a. An inventory should be taken of the degree to, and manner in which, demographic processes have been incorporated in EIAs or statements in the United States or in other immigrant-receiving countries.

   b. A comparison of PEMS and other demographic accounting systems should be undertaken to assess the degree to which statistical systems embody consistent or complementary concepts of population growth and migration.

   c. Specific analysis should document the temporal and spatial context of EIAs and monitoring systems.

2. Analysis of assumptions in environmental methodologies concerning causal determinants and correlates of environmental outcomes should be conducted to reveal the degree to which models of environmental change are completely specified.

a. Strategies for incorporating hypotheses concerning migration and environmental change and consequences in environmental methodologies should be considered.

3. Analysis of alternative research designs for the study of immigration-environmental relationships should be undertaken.

INFORMATION REQUIREMENTS FOR STUDYING THE ENVIRONMENTAL CONSEQUENCES OF U.S. IMMIGRATION

Introduction

The specification of data needs should be guided both by theory and by the important policy questions concerning U.S. immigration and the environment. While the emphasis of this report is generally on the relevant research concerning immigration, it is important to note the serious concern among environmental scientists about the status of environmental data for the United States and the capacity for monitoring environmental quality and resources for different geographic areas.

Colthern has critically addressed the need for a more coherent statistical base for environmental monitoring and comparative risk assessment (Colthern 1993b:3-10; see also Day 1993; Bunt 1992; Milliman 1992; Burnett 1992). Rosenbaum (1991:60) has raised similar issues specifically for the United States:

> One of the nation's major environmental problems remains the neglect of basic research on environmental quality. Almost all current evaluations of environmental quality are compromised in some way by missing data, constricted time frames, and incompatible measurements. At times, estimates of environmental conditions, or the risks from human or environmental exposure to chemical substances, or predictions about future environmental trends must be made on the basis of data so meager that predictions are little more that the scientists' best guess. Data essential to understanding basic environmental trends, the kind of information "everybody should have," often nobody has. Frequently, the data were never created.

Sadik (1989:5) has called for the incorporation of environmental accounting in economic reports and forecasts. McCall (1985:133-34) also describes the need for baseline data on local environmental processes in developing societies.

Fundamental to the analysis of population and the environment, however, are data concerning the components of population change—fertility, mortality, and migration—for regions and communities. Further, because the focus of the present policy debate concerns the impact of *alien* migration, disaggregation of demographic processes by immigration status is also a necessary characteristic of statistical information. Accordingly, the general focus here is on the adequacy of U.S. data on population processes for the measurement of the role of alien immigration in population trends and dynamics on the national, regional, and local scales of analysis.

Problems in the adequacy of national demographic accounts for the comprehensive measurement of trends and components of population change have been well documented (see Valdez, et. al. 1993; Levine, Hill & Warren 1985; U.S. General Accounting Office 1988; Teitelbaum 1986; for a comparative analysis of international migration statistics, see Kraly & Gnanasekaran 1987). Three sets of issues pose particular problems for the empirical evaluation of the role of immigration in environmental processes. First, conceptual problems exist in official data on alien immigration to the United States. While collected on a continuing basis, U.S. statistics on immigration suffer from problems in validity and reliability in representing demographic concepts of international migration and mobility. Second, U.S. statistics on international migration lack closure: it is not possible to assess the impact of alien immigration on population growth in an area if not all sources of population change are known. No systematic source of data exists on the process of out-migration of aliens or citizens from the United States; measurement of levels and patterns of undocumented migration relies on demographic estimation. Third, and related to the first two issues, alien migration as an annual component of population change is not easily measured at all relevant geographic scales of analysis. Decennial census data do provide very useful data at ten-year intervals; intercensal measures of immigration and local population change are available from Current Population Survey data, however, for large states and metropolitan areas.

Reasons for the persistence of problems in international migration statistics for the United States derive largely from the separation of responsibilities for demographic accounting among federal agencies and programs that differ in mission, resources, and priorities for demographic research. Most industrialized nations, in contrast, have central statistical offices in which data collection, analysis, and dissemina-

tion are coordinated. The absence of a comprehensive population policy is also a critical influence on the status, organization, and management of national demographic statistics. It is also important to add that the United States is not distinctive in the persistence of weaknesses in statistics of international migration. International migration statistics generally are recognized by many nations, both developed and developing, as the weakest component of national population accounts; the lack of international comparability in international migration statistics is also a source of multilateral concern (United Nations 1985; Kraly & Gnanasekaran 1987).

Conceptual Issues

As discussed in the previous section, the effect of immigration on the environment must be considered within the context of, or relative to, other components of population change for specified geographic areas in the United States. Ideally, this requires a demographic perspective guiding the measurement of the process of international migration to and from the United States in which demographic characteristics, specifically length of stay or departure, are documented for all migrants. To address immigration policy issues, citizenship status and category of visa also must be known along with the full battery of social and economic characteristics, including age, gender, education, household composition, occupation, employment status, income, etc. Clearly, information must be collected for states and local areas and made available for comparative analysis of population dynamics for current time periods. The ideal system of social demographic accounts remains beyond reasonable grasp. It is useful, however, to dwell on the first conceptual issue—the degree to which U.S. immigration statistics represent demographic concepts of international migration.

Statistics on international migration to the United States are collected on an ongoing basis: the U.S. Immigration and Naturalization Service [INS] is mandated to inspect every person seeking entry to the United States. Primarily because of this mission to enforce the Immigration and Nationality Act, official statistics generally reflect legal and administrative categories: U.S. citizen; permanent resident alien; nonimmigrant; refugee; asylee; and parolee. Data on admissions of permanent resident aliens usually serve as the measure of annual international migration to the United States. These statistics, however, refer to date or year of admission to the status of permanent resident alien and not year of actual arrival in the United

States. In many years, the proportion of immigrant admissions that is composed of adjustments of temporary migrants or nonimmigrants to permanent resident is on the order of 35-40 percent. In 1992, for example, 47 percent of immigrant admissions were aliens adjusted from other statuses; a large proportion of these were persons who had been in the United States at least since 1982 and were adjusting status under the provisions of IRCA (U.S. Department of Justice 1993).

Work has been done to manipulate INS administrative data to better represent demographic concepts of international migration (Kraly & Warren 1991, 1992). Data on new immigrant arrivals, arrivals of nonimmigrants who ultimately adjust to permanent resident status, nonimmigrants who remain in the United States for more than one year and subsequently depart, and refugees and asylee approvals have been combined by calendar year of entry to measure the concept of long-term immigration, a statistical concept recommended by the United Nations Statistical Commission (United Nations 1980). Comparison of data measuring this demographic concept with official INS data on admissions yields important differences in the national origins characteristics of annual alien immigration to the United States and, perhaps relatively more salient to this discussion, patterns of geographic distribution. Large absolute differences in immigration levels have been shown for New York, California, Illinois, and Massachusetts, with large relative differences in levels for smaller areas, notably the District of Columbia.

This work reveals important differences between alternative measures in the magnitude of the demographic effects of immigration for U.S. regions and states. Whether INS will continue to experiment with producing measures of long-term immigration to compare with administrative measures is not known. As mentioned above in the discussion of theory, it may also be useful if data on length of stay of nonimmigrant aliens were analyzed to measure demographic impact using person-years concepts for specific categories of nonimmigrant aliens for major places of destination in the United States.

The U.S. Census Bureau also combines different sources of data, including INS administrative data, to operationalize the concept of net immigration in its program of population estimates and projections (see, for example, Word 1993). The concept of net immigration includes six categories of international migrants for which data are collected or estimated for estimates of annual population change for intercensal years and to operationalize the concept of net immigration for national

population projections. The categories include legal alien immigration, undocumented alien immigration, foreign- and native-born emigration, net migration from Puerto Rico, net movement of armed forces personnel and dependents, and net movement of civilian federal employees and dependents. By seeking to measure international migration on the basis of residence criteria of the decennial census, the concept of net immigration is more relevant for demographic analysis of population change. By omitting some categories of international migration, however, the validity of net immigration as a demographic concept fall shorts. For example, international migration *to* the United States of nonfederal employees and dependents and increasingly important, categories of nonimmigrants with long-term length of stay in the United States (e.g., students and foreign government officials) are not represented in the concept of net immigration (Word 1994).

Closure in Demographic Accounts

Migration from the United States is not directly measured in the federal statistical system and as a result we have no comprehensive source of statistics on emigration from the United States (Warren & Kraly 1985; Edmonston 1989: 30-36; Kraly & Warren 1991). The measurement of emigration of immigrants and the foreign born derives primarily from residual methods of estimation (Warren & Peck 1980; see also Warren & Kraly 1985). In the past few years, the U.S. Census Bureau has explored the use of multiplicity techniques to estimate emigration using the Current Population Survey [CPS] (Woodrow 1991; Woodrow 1990). Other attempts to estimate emigration of immigrants have relied on linkages among administrative data sets (see Jasso & Rosenzweig 1982). Each of these analytic approaches, however, provides data that are of limited usefulness for the measurement of emigration of either aliens or U.S. citizens from the United States at either the national or sub-national levels or for documenting changes in emigration patterns over time.

There has been consideration of other federal sources of administrative data as a basis for estimating emigration (see Levine, Hill & Warren 1985; Edmonston 1989; Kraly 1991). Social Security files hold promise for the estimation of outmigration from the United States of U.S. citizens and alien workers in social security-covered employment and social security beneficiaries; U.S. Department of State records on U.S. citizens who have regis-

tered at U.S. consulates may be useful for monitoring changes in the size and distribution of the expatriate community; the Nonimmigrant Information System has been shown to be an effective source of information on length of stay of temporary migrants to the United States (see Warren 1990, Kraly & Warren 1991); and the passenger surveys conducted by the U.S. Travel and Tourism Administration may provide a useful sampling frame for survey of intentions concerning departure and residence abroad (Kraly 1991).

No direct data, other than statistics on apprehensions, are available to measure level, trends and characteristics of undocumented alien migration to and from the United States. As with alien emigration, estimates of undocumented migration have been computed using residual methods of demographic estimation for U.S. census data, immigrant data records of the INS, estimates of emigration, and census undercount and assumptions about mortality levels. Reliability of estimates of undocumented migration is thus challenged by the nature of error in measuring the other components of population change, notably legal alien immigration and emigration.

Research by Warren and Passel (1987) has provided the conceptual framework for subsequent development of estimates of undocumented migration (see, for example, Passel & Woodrow 1987; Woodrow & Passel 1990). Increasingly apparent, however, are constraints on the methodology to provide reliable estimates, particularly at the subnational level. Error in the estimates reflects problems in assumptions about emigration and coverage error in census enumeration and in measuring nonimmigrants and agricultural workers with long-term length of stay in the country (Woodrow 1992). A different estimation methodology using INS data has been applied by Warren to develop estimates of overstay among aliens admitted on nonimmigrant visas, by country of origin (Warren 1990). Extending this analysis, Warren has also estimated the size of the undocumented alien population by state of residence (see Warren 1994a).

Availability of Data for Regional and Local Analysis

These issues concerning the conceptualization and measurement of the process of international migration *to and from* the United States hamper the analysis of the components of population change on the national level. These issues are also rel-

evant for the measurement of the components of population change for states, regions, metropolitan areas, and local communities throughout the United States. As discussed earlier, the issue of geographic scale is critical to rigorous study of the role of population and immigration in environmental change.

The lack of direct data on the place of residence and internal migration patterns of immigrants poses particular problems for analyses which seek to relate flow statistics on alien migration to population characteristics for regional or local areas. For example, the Population Estimates Program of the U.S. Census Bureau incorporates international migration into estimates of annual population for states and counties in the United States using the geographic distribution of previous alien immigration streams. Estimates of annual net immigration are derived from both direct measurement of some categories of alien immigration (e.g., permanent resident alien immigration refugees and nonimmigrants adjusting to permanent resident status) and indirect estimates of other categories (e.g., net undocumented migration and foreign-born emigration). The estimates are allocated to states and counties on the basis of the geographic distribution of alien immigrants, by selected region and country of birth, for alien residents in the United States entering in the five years prior to the decennial census. Assumptions about geographic distribution become increasingly out-dated for measures of annual population growth at the end of the censal decade (see Word 1993).

INS statistics do document intended state and city of residence for immigrants and nonimmigrants admitted to the United States. The reliability and validity of these data on residential intentions, however, are not well understood (see Kraly & Hildebrandt 1993). For the most part, demographers must rely on decennial census data for such analyses using fixed period data on residential change (see, for example, Frey 1994; also Plane & Rogerson 1994:91-95). Census data on previous residence abroad are not ideally suited for the analysis of the demographic impacts of alien immigration for local populations. The temporal limitations of decennial census data also inhibit the measurement of the components of local population change. Increasingly, state and city planners have turned to other administrative sources of data to tap the role of migration in local population dynamics during intercensal years (see Weeks 1992 :492-96; see also Heer & Passel 1987).

Implications for Research on U.S. Statistical Information Concerning Population Immigration and the Environment

It is productive to continue to evaluate issues concerning the measurement of the international migration component of national, regional, and local population dynamics. But to summarize, several issues emerge from this brief review of general problems in U.S. immigration data, each of which has serious implications for the analysis of the relation between immigration and the environment. There exists a lack of a demographic conceptualization of international migration and mobility inherent in INS information systems, the primary source of data on the flow of international migration to the United States. As a result, there is lack of congruence between INS statistics and demographic data collected through the decennial census or the CPS. Comprehensive population characteristics and patterns of in- and out-migration for local areas are measured at ten-year intervals through decennial census data; the Current Population Survey generates very valuable data for intercensal periods on the role of immigration in population change but only for the nation as a whole and the largest states and metropolitan areas. Finally, lack of closure exists in demographic accounts, notably, the absence of data on emigration from the United States, the international mobility patterns of U.S. citizens, and undocumented migration patterns.

As stated earlier, the nature of the problems in U.S. statistics on international migration for purposes of demographic analysis of national and local population change are relatively well documented. Left unspecified, however, is the nature of the information necessary to determine the environmental impacts of population and migration trends given appropriate demographic data. As embodied in the models of population-environmental dynamics discussed earlier, such "mediating factors" include behavior patterns concerning consumption, production, and conservation among immigrants and internal migrants and residents, as well as such contextual characteristics as industrial mix, patterns of economic and technological change, political organization, and policy and program implementation (see also Ness, Drake & Brechin 1993c:377-406). Moreover, specification of data needs also assumes a clear identification of relevant environmental outcomes for a specific locale, region, or metropolitan area

(see Rosenbaum 1991:60-61; Day 1993; Risler 1993; Colthern 1993b).

A longitudinal survey of immigrants holds strong potential as a means to collect data more effectively on the social demographic behavior and experiences of immigrants. The research community has recognized of the value of a survey on immigrants to study directly patterns of settlement and internal mobility among immigrants, as well as social characteristics and economic behavior among immigrant cohorts and how these change over time. Valdez, et al. (1993:2-3) recognize the need for more appropriate data to address the complicated policy questions concerning U.S. immigration and argue strongly for the use of survey methodology to assess the impacts of immigration on regional and local communities (see also Chokor 1985:18). Their study of Salvadorean and Filipino communities in Los Angeles represents an important effort to use survey methods to document the role of immigration in social, political, and economic processes in local areas.

The use of social survey methodology is also highly appropriate for the collection of data concerning environmentally-relevant behavior, attitudes, and impacts of immigrants. To yield results appropriate to environmental research, however, survey design must address, first, the need for reliable data at different geographic scales and, second, the critical need to compare over time behaviors and characteristics among different groups of immigrants and with U.S. citizens. Similarly, survey results also must foster the comparison of causes and correlates of environmental change in geographic areas experiencing different levels of in- and out-migration, including areas lacking significant alien immigration.

Certainly, there is a great deal of work remaining to develop a comprehensive statement concerning the nature of information and methodologies appropriate for the study of the role of population, and specifically immigration, in environmental processes and change in the United States. Several initial recommendations for policy relevant research clearly emerge, however, from this initial review of information requirements. The recommendations that follow generally focus on the requisite needs for improving the statistical basis for measuring the role of immigration in population change at different scales of analysis; complementary issues should be addressed concerning the status of data on environmental change for places and regions in the United States.

Recommendations for Improvements in Data

1. An inventory and comprehensive description should be conducted to document the availability and accessibility of data on environmental processes, quality, and resources for the regions, states, and metropolitan, urban, and local areas in the United States.

2. An inventory and comprehensive description of demographic data available to measure regional, state, and local population dynamics (births, deaths, and migration) for different periods of time (intercensal, annual, etc.) should be developed; social demographic characteristics of population (age, sex, education, occupation, country of birth, length of residence, etc.) that are available also should be identified.

   a. Documentation should be made of the degree to which alien immigration can be identified as a component of population change at different geographic scales and for different periods of time.

   b. Documentation should be made of the degree to which sources of internal migration, both in-migration and out-migration, can be identified as components of population change at different geographic scales, for different periods of time and for immigrants and U.S. citizens.

   c. Documentation should be made of the degree to which sources of emigration from the country can be identified as components of population change at different geographic scales, for different periods of time, and for immigrants and U.S. citizens.

2. Data available for the measurement of the components of regional and local population change should be evaluated in terms of both validity and reliability.

3. The implications of different concepts of migration, for example, administrative measures versus demographic concepts, should be evaluated empirically for the measurement of regional and local population change.

4. An exploration of the collection or use of alternative sources of population and migration data for measuring local and regional population change should be initiated.

a. Evaluation should be conducted of the use of sampling techniques in estimation of components of population change for different geographic scales.

b. Evaluation should be conducted of the use of survey methodology for the estimation of components of population change for different geographic scales.

c. Analysis of the degree to which proposals for a longitudinal survey of immigrants can address issues concerning environmental impact should be conducted.

5. Research on data availability should be coordinated with analytic efforts by environmental scientists to identify regions, places, and locales in the United States for which study of population, immigration, and environmental relationships is particularly salient.

CONCLUSIONS

The general criticism of Meyer and Turner (1992:51) concerning the state of scholarship on human impacts on the global environment is particularly useful in assessing the current state of scholarship on U.S. immigration and the environment:

> Two extremes in approach are ultra-empiricism and ultra-theoreticism. In the former vein, Newell and Marcus [1987] present a correlation of +0.9985 between world population growth and tropospheric CO_2 since the 1950s as proof of population's fundamental role. In the latter, Harvey [1974] deprecated neo-Malthusian arguments for the primacy of population growth in resource depletion as politically founded. The former is apt to mistake correlation for cause (or absence of correlation for causal unimportance) in a highly complex area; the latter is apt to narrow excessively the scope of investigation without recourse to data. Theory—including theory from the social sciences—and evidence need both to be drawn upon.

This review has sought to develop recommendations for scientific research on U.S. immigration and the environment that address the salient analytic issues identified by Meyer and Turner. Four broad themes emerge from the specific recommendations set out in each section of the review.

Research on the environmental consequences of U.S. immigration will benefit

from first, attending to the adequacy of conceptual models of the population-environment relationships, and more generally, perspectives on human environmental impacts, in specifying the role of migration in processes of environmental change. On the basis of this review, it is apparent that theoretical development concerning migration and the environment needs to occur in order to derive relevant and testable hypotheses about causal relationships and effects.

Second, given the significance of geographic scale for empirical findings about the relationship between demographic processes and environmental change, studies for the United States should be initiated on national, regional, and local levels. Results of studies should be interpreted with an explicit appreciation of the differences in the effects of population dynamics for environment processes at different geographic scale: "[Popu-lation's] connections to land-cover change become weaker at increasingly smaller spatial scales because of the importance of the other variables that affect demand or spatially deflect its impacts" (Meyer & Turner 1992:54). Similarly, research results should synthesize the effects of immigration processes spatially, among regions and local areas, and, structurally, across economic sectors.

Research on U.S. immigration and the environment should provide both descriptive results concerning trends in demographic and environmental change at different geographic scales and for specific places, as well as causal insights about the nature of relationships among factors. It is critical that analytic attention be devoted to studying the implications of research design for the production of useful and relevant information for improving our understanding of immigration and environmental processes. Specifically, research results must be relevant first, for the accumulation of knowledge about interrelationships among population, migration and the environment in the United States and second, for the analysis of national policies concerning immigration, population and environmental protection, and programs to allocate federal resources among states and localities. In other national and regional contexts, survey methodology has been shown to hold useful analytic potential for explanatory studies of migration and environmental change and should be explored for the U.S. context.

Finally, the statistical foundation for the analysis of the environmental consequences of U.S. immigration must be strengthened. Migration statistics—data on alien immigration, internal migration

and emigration—must be improved to accommodate local and regional analysis for intercensal periods. As relevant in these times of fiscal restraint in federal spending is the critical need to advocate the continuation and maintenance of current statistical programs: INS statistics on the admission of aliens to the United States must continue to be collected and made accessible for public use; questions concerning nativity, citizenship, and geographic mobility must continue to be asked on the decennial census and the Current Population Survey. Finally, an assessment of the status of indicators of environmental quality and resource availability is a critical component of developing an agenda of policy relevant scientific research.

These broad recommendations beg the question of strategy for stimulating and organizing research efforts to address the important analytic issues concerning U.S. immigration and the environment. Interdisciplinary collaboration is essential for the development of a research program on U.S. immigration and the environment (cf. Preston 1993:600). Interaction among environmental and social scientists must be facilitated to initiate theoretical development, to reflect on research design, and to document the status of available data, and ultimately to establish a framework for interpretation of research results in connection to the policy process.

Given the need for both baseline documentation and exploratory research, it seems highly appropriate to initiate a research program on population, immigration, and environment for specific regions, metropolitan areas, and local communities in the United States. Selected places should be identified as research sites in which an integrated program of research on population dynamics and environmental processes would be implemented. Interdisciplinary collaboration among scientists must be organized within research sites and coordinated with relevant planning and scientific agencies at the federal, state, and local levels. Taken together, national and local priorities for environmental planning and management, national goals for immigration policy, and local needs for population forecasting underscore the importance of a coordinated research program concerning population, immigration, and the environment for regions and communities in the United States.

A Final Observation

Barry Commoner (1975:111) once stated that he knew ". . . of no scientific principle which can tell us how much to rely on population control and how much on

technological change (and the required economic controls) in order to reduce environmental impact. The choice between these alternative paths is clearly a political one, not a matter of science." A somewhat contrasting perspective, inherent in the analysis presented here, holds that research on the relationships between U.S. immigration and the environment is an essential component of rational and honestdecisionmaking concerning U.S. immigration. "Green" arguments are currently more acceptable than the ethnocentric rationale for restrictionism of Colgate's President Cutten (Wood 1923). Whether environmental criteria are appropriate grounds for revising immigration policy encompasses questions that are within the grasp of social and environmental research.

Abstract

This paper analyzes major developments in European migration policies over the last decades with an eye towards U.S. public policy concerns. It summarizes trends in legal immigration, legalization policies, policies towards asylum-seekers, temporary foreign worker admissions, and measures taken to curb illegal migration.

Western European states have developed a limited capacity to deter illegal migration through such measures as employer sanctions, carrier sanctions, visa policies, reform of asylum policies. These measures will continue to be incrementally strengthened. However, they cannot hermetically seal Europe. Despite statements like the French Minister of the Interior's call for zero immigration, legal immigration will continue—as will some illegal migration. Further steps will be taken to enhance integration of legally resident aliens, who are the most affected by illegal migration.

Rising unemployment and economic restructuring have disproportionally affected foreign workers in Europe. Their employment characteristics are very different today from what they were in the 1970s. Despite employer calls for a return to guestworker and seasonal worker policies, there does not appear to be a prospect for massive recruitment of foreign labor. There also is no serious prospect for rollbacks on migrants rights achieved in the 1970s. Support for anti-immigrant parties may have crested and does not seriously challenge democratic institutions. There exists a dense web of bilateral and multilateral treaties that will prevent achievement of zero immigration.

This paper seeks to dispel exaggerated notions of *Voelkerwanderung* and of gestapo-like treatment of aliens in Europe. It reveals a remarkable convergence in migration policy concerns between Europe and the U.S. at a time when transatlantic coordination on migration issues is urgently needed. Europe confronts enormous challenges in the migration area. Situations like Algeria are most worrisome. But uncontrollable mass migration has not bowled over Europe. Instead only a fraction of the migrants who aspire to take up residency there make it.

Introduction

President Clinton's moving visit to Western Europe in early June 1994 reaffirmed long-term United States interests in European democracies and in further development of transatlantic partnership. Within this context, it seems imperative for Americans and Europeans, as well as the

rest of this interdependent world, to arrive at an accurate assessment of Europe's migration problem. There are several reasons why Americans, in particular, should be concerned.

First, regulation of international migration arguably is Europe's most pressing domestic and foreign policy issue. Other competing priorities, such as Europe's alarming unemployment, often are bound up inextricably with the migration issue. Given global realities, there is no reason to expect international migration regulation concerns to diminish over the short to medium term. Indeed, prospects for the twenty-first century in this regard are most daunting. If not dealt with in a constructive, comprehensive, and sustained manner, the international migration issue risks endangering Europe's democratic institutions, appreciably destabilizing societies, and adversely affecting Europe's ties with other regions. Europeans increasingly view international migration as affecting their national security (Hamilton 1994). Americans must take note of this, as what affects European security indirectly affects us. We have a long-term and vital stake in European security.

Second, Americans are in the same boat as Europeans. For all the differences in our respective immigration histories, we confront similar long-term challenges in the realm of international migration. A palpable convergence in U.S. and European immigration issues and concerns has occurred since World War II. These similarities make European policies on international migration instructive, although analysis must be guarded and nuanced both by appreciation of underlying and often highly significant transatlantic differences and by variations within Europe.

In this regard, two images of Western European response to the international migration challenge are unsettling. One portrays Western European and other Western democracies as unable to prevent illegal migration. The most extreme version of this image is conjured up by the German term *Voelkerwanderung*—the barbarian invasions. This term re-emerged in the aftermath of the collapse of Communist regimes in Eastern Europe. The tottering Soviet government helped propagate the image as part of a gambit for increased assistance (Brubaker 1992). Essentially, the message was, "Help us or millions of us will descend upon you." This recalls Mexican President Salinas' often repeated remark that the U.S. will either get Mexican tomatoes or Mexican migrants.

The *Voelkerwanderung* image, however, is not to be dismissed lightly. It is taken

very seriously by more than a handful of respected immigration scholars (Cornelius, Martin & Hollifield 1994). In its academic version, the image holds that Western European and other Western democracies currently are, and will be, unable to cope with international migration. The immigration control strategies of Western democracies are flawed and fated to fail. The deep structural forces at work in the international economy and in global society are such that immigration control measures are more symbolic than real. International migration essentially is a function of employment demand. Democratic states can do little to correct or adjust continuing employer demand for cheap foreign labor. Hence, the flows will continue in one form or another. As one high-ranking French official phrased it, "One closes the door but opens the windows." Viewed through this optic, immigration control strategies serve mainly to legitimate the state but they ignore or obscure the realities of illegal migration.

The scenario of mass uncontrollable migration is disquieting for manifold reasons. It fuels right-wing extremist parties that advocate draconian measures, not only to stop illegal migration, but usually also to roll back the rights of resident aliens and even of the rights of certain freshly naturalized citizens. The most extremist envisage mass involuntary repatriation of "unwanted aliens"—particularly Muslims. The appeal of anti-immigrant politics, in turn, frustrates integration policy goals by deepening the chasm separating immigrant and nonimmigrant communities. Moreover, the notion that little can be done by governments to prevent illegal migration has insidious effects on the credibility of governments and adversely influences the morale of those charged with the implementation of public policies. In brief, the image threatens to become a self-fulfilling prophecy if officials and publics at large come to view governmental policies as doomed to failure or, worse yet, as orchestrated hypocrisy.

The second image or scenario is the converse of the first. Western Europe has become a *Fortress Europa* of draconian immigration policies, hermetically sealed borders, and oppressive measures towards all immigrants—illegal, resident alien, or naturalized citizen (Ireland 1991). Key to the *Fortress Europa* image is an interpretation of mainstream Western European political parties and their electorates as afflicted by contagion from the extremist, anti-immigrant right. Parties and leaders with generally principled and constructive stands on immigration are portrayed as pandering to xenophobia. Measured efforts to prevent illegal immigration or render inevitably restrictionist policies

more effective are interpreted as racist or neo-Nazi in inspiration. Legitimate distinctions between resident and nonresident aliens are obscured in order to denounce the alleged callousness of governments and their contempt for the human rights of migrants. In this second image, migrants themselves seem incapable of doing wrong and Western European governments incapable of immigration restriction consistent with human rights and democratic norms.

If this second image were accurate, the cornerstone of America's relationship with Western Europe would be in jeopardy. Democratic societies falter when there is systematic disregard for human rights and persistent legal status inequality. The rule of law would be in doubt. One could expect the massive migrations of the post-1945 period to end in Spartacus-style revolt or sullen acquiescence to a new form of apartheid.

Fortunately, both commonplace images badly distort contemporary Western European immigration realities. Moreover, there appears to be only a remote chance that either scenario will come about in the future. One cannot completely rule out anti-immigrant extremist parties achieving power one day. If the National Front in France or the Republikaners in Germany were to achieve power, the democratic nature of those two societies would very much be in doubt. However, even in this most extreme and unlikely scenario, international constraints, the enmeshing of these states within the European Union and NATO, as well as other bilateral and multilateral treaties and relationships, make effective implementation of extreme anti-immigrant policies, such as the National Front's 50- point program, dubious.

Despite the outcome of the most recent Italian general election, the spectre of a resurgence of the extreme right in Western Europe has been blown out of proportion. There are ample grounds for vigilance and worry, particularly with regard to rising anti-immigrant violence in some countries. But most voters for extreme-right parties are not committed ideologues (Veen, et al. 1993). Rather, many are protest voters fed up with perceived governmental laxity in immigration matters, particularly vis-a-vis asylum-seekers. The perception of laxity is incongruent with the image of *Fortress Europa*, but it probably is more consistent with the facts than the latter image. Western European governments were unprepared for the asylum-seeker influx and it took them a decade or more to adjust. But steps have been taken to reduce abuse of asylum and these measures have had results. This should weaken the appeal of

anti-immigrant extremism in the future. Recent elections suggest that support for the National Front in France may have crested at 15 percent of the electorate.

The spectre of mass uncontrollable migration and the related notion of democratic state incapacity to regulate international migration also cannot be dismissed readily. Western European states do face daunting challenges in regulation of international migration and many of their control efforts to date have been inadequate. Some Western European states appear more effective than others in this respect (Freeman 1994). Substantial illegal immigration to Europe continues two decades after the onset of serious efforts by Western European states to curb illegal immigration. But the apocalypse has yet to happen. Indeed, it is very difficult to ascertain how extensive illegal immigration is, although the figure of 2.6 million illegal residents within the European Union has gained credence.[1]

Estimates of illegal immigrant populations are educated guesswork and often are made to suit political purposes, whether it be to embarrass a government or a political rival or to discredit efforts to curb illegal migration. The indeterminate nature of the illegal alien population renders interpretation of Western European efforts to control illegal immigration much more akin to an art than a science and condemns scholarship in this area to unrelenting controversy. Nonetheless, it seems fair to observe that much more is known about illegal immigration to Western Europe today than two decades ago. Indeed, improved understanding of what might be termed the sociology and political economy of illegal migration constitutes a major reason for believing that Western European states will be able to cope with the challenge of international migration in the twenty-first century.

Key Trends in Migration to Europe since 1970

The great watershed events in the post-1945 history of international migration to Europe were the domino-like decisions from 1972 to 1975 to curb most further foreign worker recruitment. These curbs did not apply to community workers in various member states of the European Community, nor within the Nordic Community, and there were other exceptions, such as continuing recruitment of seasonal foreign workers in France and Switzerland. Roughly concurrently with the re-

[1] The estimate is W.R. Boehning's—the ILO's migration specialist and the leading authority on migration to Western Europe (Salt, et. al. 1994).

cruitment curbs, Western European states—some more grudgingly than others—came around to acceptance of the principle of family reunification rights for resident aliens. In some instances, significant family reunification had occurred prior to the recruitment curbs. Indeed, this growing reality contributed to decisions to stop or curb further recruitment. European governments belatedly began integration policies. Acceptance of family reunification was viewed as part and parcel of integration. The third prong in Western European policymaking at this juncture was the advent of an effort to deter illegal migration. Recruitment curbs, integration of resident aliens and their families, and prevention of illegal immigration became the cornerstones of policy in most Western European states. The overarching goal was stabilization, if not reduction, of alien populations.

For more than a decade, a rough stabilization did occur. This did not mean international migration to Western Europe stopped or that alien populations themselves were immutable. To the contrary, considerable legal immigration continued in the form of family reunification. Some scholars have chosen to interpret post-1972 family reunification as evidence of governmental incapacity to regulate international migration. But, for the most part, this interpretation is misleading, despite the discomfiture of many governments and the currency gained by terms like "immigration stop" and "sealing the borders" (Hollifield 1993; van Amersfoord & Pennix 1994). Foreign worker settlement meant that all Western European states became de facto immigration lands insofar as they recognized a right to family reunification.

As far as resident alien populations were concerned, while overall numbers stabilized, their characteristics changed significantly from 1975 to 1985 and even more so thereafter. The key trends were contraction of alien populations from nearby European countries offset by growth of populations from more culturally and physically distant countries. The number of Spaniards in Germany declined while the Turkish population grew.

Whereas in Western Europe there were roughly two employed to one economically inactive alien residents prior to 1970, this ratio was reversed by the mid-to- late 1980s, partially because of the continuing arrival of foreign worker dependents and of births to resident aliens. But alien unemployment was rare until the recession of the mid-1970s. By the 1980s, as suggested by **Table 1**, rates of foreign worker unemployment typically far exceeded rates for citizens. Foreign workers were disproportionally adversely affected by the

massive layoffs stemming from recession and economic restructuring after 1973. This was due to their concentration in employment sectors particularly vulnerable to recession, such as the building industry, as well as their generally lower levels of professional qualification and education. For instance, many of the foreign workers in automobile manufacturing had been recruited for assembly line work. When robots replaced teams of finishing painters in plants like Renault-Flins, the unemployed foreigners had few prospects for reemployment in industry or for retraining. Most lacked the educational background to find employment in computer-assisted manufacturing (Miller 1986a).

The growth and persistence of resident alien unemployment profoundly affected Western Europe. It contributed to the growth of anti-immigrant movements. One of the paradoxes of the period from 1975 to 1985 is that massive resident alien and citizen unemployment did not end the illegal migration and illegal alien employment that had become significant in a number of Western European states prior to 1973. One key factor behind this was the difficulty of rapidly altering employer behavior. As many foreign workers gained more secure legal status, their rights of residential and labor market mobilty increased. For example, during this time many seasonal workers in Switzerland acceded to resident alien status.

As they did, they left their jobs for better paying and more attractive (e.g., day jobs rather than night shifts) employment. The key to any seasonal worker or guestworker program is to restrict the labor market and residency mobility of foreign workers, thereby ensuring certain employers access to labor outside the wage and working conditions constraints set by normal national (and now regional) labor market mechanisms. At the same time, Swiss employers faced dwindling access to legal seasonal labor as their government, under considerable political pressure from anti-immigration campaigns throughout the 1970s, reduced annual contingents of seasonal workers. Seasonal foreign worker admissions fell from 206,000 in 1964 to 90,000 by 1976 (Miller 1986b). Many Swiss employers probably illegally hired foreign workers rather than restructure their employment practices.

Hence, the paradoxical coexistence of high resident alien unemployment and continuing illegal alien employment arose. Some governments began efforts to improve manual labor conditions, such as the French in their *revalorisation du travail manual* program of the mid-to-late 1970s, but the effects of several decades of massive foreign worker recruitment upon labor markets and employment practices could not be undone quickly. It is difficult to say whether employer recourse to illegal alien labor rose or fell across Western Europe from 1975 to 1985 as compared to the previous decade. The suspicion is that it fell in France but rose in Germany and Switzerland.

Another key change in employment characteristics was the dramatic increase in foreign labor employment in service industries and the decline in the traditional sectors of foreign worker concentration—manufacturing and construction. The French data in **Table 2** are emblematic of a broader trend. The implications of this massive shift for nascent European efforts to curb illegal immigration are important. Aliens increasingly found employment in firms and sectors more prone to illegal alien employment. Additionally, the development of temporary employment, manpower leasing, and—more generally—greater flexibility in labor market and management practices created new and more extensive illegal employment opportunities. The decline of unions probably was both a cause and an effect of these trends.

This decade of stabilization also witnessed the affirmation of Islam. This was part and parcel of the settlement process. As more and more immigrants gained secure residency and employment rights and as prospects for return home dimmed, they built mosques, formed

Islamic associations, and created Islamic educational and cultural institutions. This affirmation was aided in many cases by Western European governments and employers, in some instances as part of integration policy, in others to forestall the appeal of trade unions and radical political movements (Kepel 1987). Homeland governments and states like Libya and Saudi Arabia also played key roles. There were violent spillovers of homeland politics to Western Europe as well as the penetration of Islamic fundamentalism. Many Western Europeans, in mounting apprehension over the long-term political integration of Muslim immigrants, viewed this religious affirmation with alarm. The anti-immigrant movements of the 1980s and 1990s often had anti-Islamic as well as antisemitic overtones.

Another hallmark of the stabilization decade was a North-South convergence within Western Europe. The countries of massive emigration in Southern Europe prior to the 1970s became significant countries of immigration. In part, this was due to closing of the development gap between countries like Italy and Germany within the European Community. In part, this was due to the recruitment curbs instituted in Northern Europe. Foreign workers, who might have gone to France or Belgium in the 1960s, went to Italy or Spain instead.

Within a decade, Spain, Italy, Greece, and even Portugal became immigration lands in their own right and confronted many of the immigration control questions faced by their partners to the North. This inter-

European Community convergence in immigration circumstances, while very uneven, created more of an objective basis for inter-European state cooperation and coordination on questions and issues of prevention of unwanted immigration than earlier. Nevertheless, enormous differences between Western European states persisted by the mid-to- late 1980s in migration policy and the Southern European states generally manifested less alarm over international migration than Northern Europe. There may be empirical reasons for this; annual rates of legal migration vary sharply in Western Europe, from more than 1 percent per year in Germany (more than 1 million newcomers in a population of 81 million), to 0.5 to 0.6 percent in the Benelux and Scandinavian countries, to 0.1 to 0.3 percent in Southern Europe.

For all the North-South convergence, Italians, Spaniards, Greeks, and Portuguese tended to view international migration somewhat differently and more generously. Their permeability to illegal immigration and the relative complacency about it deeply worried immigration officials in such countries as France. Ultimately, this disjuncture would impede efforts by European Union member states to coordinate policies towards illegal immigration in the 1990s. While the spring 1994 postponement *sine die* of the elimination of international frontiers foreseen under the Single European Act [SEA] was attributed to technical reasons, lurking in the background were the concerns of Northern Europeans that their Southern European Union partners simply are not far enough along the path to controlling illegal immigration to risk elimination of frontier controls.

One final defining feature of the period bears underscoring, particularly in light of the *Fortress Europa* image. While Western European governments clearly became drastically more restrictive in terms of foreign worker admissions by 1975, more and more legally-admitted aliens gained greater security of residency and employment rights. This constituted a major achievement for European democracy, as it was long unclear that many foreign workers would be allowed to renew residency and employment permits. Most foreign workers secured greater residential and labor market freedom by qualifying for more favored status through continuous employment and residency.

By the early 1960s, the Swiss government for instance, had come under pressure from the Italian government to accord a more liberal status to long-term Italian seasonal workers. The 1964 revision of the Italo-Swiss bilateral labor agreement enabled more and more Italian seasonal

workers, who technically are not residents and thereby are not counted as part of the total population of Switzerland, to qualify for resident alien status. The movement for migrant rights began in the 1960s and, in some respects, resembled the civil rights movement in the United States. It made great progress across Western Europe by 1985. The French government's decision in 1984 to accord qualified resident aliens a ten-year, automatically renewable residency and employment permit—*le titre unique*—represented one capstone of a process long in the making.

The advances made in legally-admitted alien rights conferred a more liberal status upon resident aliens in Western Europe that narrowed transatlantic differences pertaining to resident alien status. While the goals of Western European integration policies were not achieved in many areas, significant progress, as attested to by the German data in **Table 3**, was made in terms of resident alien rights. Western European strategies of immigration control were predicated on the notion that prevention of illegal immigra-

Table 3.

Improvements in Residence Status of Germany's Aliens

	1982	1992
Aliens with residence permit of any kind	3,245,959	3,870,765
Aliens from non-EC countries with a limited residence permit.	1,482,9449 (=45.7%)	99,685 (=25.8%)
Aliens from non-EC countries with an unlimited residence permit.	804,975 (=24.8%)	991,799 (=25.6%)
Aliens from non-EC countries with a right of residence.	40,178 (=1.2%)	809,236 (=20.9%)
Aliens with an EC residence permit	917,862 (=28.3%)	1,070,045 (=27.6%)
Aliens with a consolidated residence status (items 3, 4, and 5).	1,763,015 (=54.3%)	2,871,080 (=74.2%)

tion was complementary to integration of resident aliens.

The Crisis of International Migration to Europe

A confluence of five factors ushered in a new period by 1990. Historical periodization is highly interpretative and seldom uncontroversial. Many of the hallmarks of the current migratory period can be traced back to the 1970s or earlier. On the whole, there was more continuity than discontinuity between what are labelled here the decade of stabilization and the current period. However, since the late 1980s, a new sense of urgency over international migration has set in. Crisis is too strong a term if one compares the contemporary situation to that which existed in Europe in the late 1930s. What the term connotes here is the growing saliency of international migration issues in domestic and foreign policies by roughly 1990.

International migration increasingly was viewed as linked to national security and moved up the agendas of high-ranking officials—including diplomats. Indeed, the idiom of the international migration specialist—terms like "boatpeople," "guestworkers," "nonrefoulement" and "asylum-seekers" that were not in most persons' vocabularies several decades earlier—increasingly had become the idiom of diplomacy. There was a marked increase in diplomatic efforts on the international migration front beyond what there had been during the Cold War era. In part, this was imputable to a long overdue redefinition of national security as the threat of East / West military confrontation waned.

The asylum-seeker influx had reached perceived crisis proportions in Germany by 1980. What is important is how rapidly asylum requests snowballed. As late as the early 1970s, as seen in **Table 4**, there were minuscule numbers of asylum-seekers. The increase was clearly linked to the recruitment curbs, but there also were numerous adverse developments in political order around the world. The global refugee population doubled in the 1980s.

Rightly or wrongly, the asylum-seeker influx undercut the credibility of Western European immigration control strategies. As **Table 5** indicates, the vast majority of asylum-seekers were not found to be *bona fide* refugees entitled to asylum. Adjudication of claims and maintenance of the claimants cost enormous sums. Further, more than one-half of those claimants denied refugee status managed to stay on,

thereby frustrating immigration control goals. The perception that asylum-seekers were circumventing the recruitment curbs through abuse of asylum provisions caused a political firestorm that today still threatens the viability of the international refugee system. Its sustainability vitally interests the United States as well as Europe.

The second factor contributing to a qualitative change was the collapse of Communist systems. Since the early 1970s — the time of the Jackson-Vanik Amendment in the United States—Western democracies had pressed for softening of the rigid mobility controls imposed by Communist governments upon their citizenries. German *Ostpolitik*, US-Soviet détente and signing of the Helsinki Accords gradually opened the door to emigration from the Soviet bloc states. During the 1980s, as seen in **Table 6**, Germany granted ever greater numbers of visas to citizens of Soviet bloc states. This outflow probably contributed to the momentous events of 1989 and 1990. Mass exit of citizens of the German Democratic Republic through Czechoslovakia and Hungary to Austria triggered a fateful chain of events that led to an East German decision to open the Wall. Within a year, the euphoria over German national reunification had given way to the spectre of *Voelkerwanderung*.

A third factor contributing to change was the progress made toward implementation of the SEA. Within the Schengen Group (established to hasten progress towards realization of a single market), discussion of the modalities of eliminating internal frontiers had advanced. While the SEA had been rapidly signed and ratified without consequential political op-

*Estimate as of May, 1990

position, some citizens feared that the elimination of internal frontier controls would result in large influxes of aliens from nearby states. The National Front in France, for instance, stoked the fear that the single market would result in a new influx of Turks from Germany, such as had happened during the legalization period of 1981 to 1983. While these fears for the most part seemed unfounded, they nevertheless contributed to a sense of unease.

The persistence of integration problems constituted a fourth factor. Immigrant disadvantage in housing, education, employment, health, and other areas was nothing new. But these problems seemed more intractable by 1990 than they did fifteen or twenty years earlier. U.S.-style urban disturbances involving predominately immigrant-origin minority populations erupted in the United Kingdom, France, and Belgium. Muslim demonstrations against Salman Rushdie shocked many Western Europeans. A growing rift between the Islamic and Western worlds increasingly seemed to rend the fabric of Western European societies. The progression of the electoral inroads of extreme right anti-immigrant parties augured poorly for integration.

And then there were the illegal immigrants. Nobody knew how many there were, but their presence in certain industries and jobs persisted despite enforcement of employer sanctions, legalizations in some countries, and other steps.

A siege mentality set in, fostered in no small part by exaggerated fears of *Voelkerwanderung*. The *Fortress Europa* image was clearly exaggerated too. That the two could co-exist in the early 1990s was symptomatic of a profound malaise. Mercifully, Europe's migration problem can, and probably will, be managed in a fashion consistent with human rights and democratic values. One can best begin to fathom this by examining the new barbarian invasion potential from Eastern Europe and beyond.

Why the New Barbarian Invasions Have Not Materialized from the East or the South

Table 7 reveals a steady increase in the numbers of East to West migrants. But many of these post-1989 immigrants are welcomed abroad. They are Jews migrating to Israel, ethnic Germans being reintegrated into German society, ethnic Greeks returning to Greece, and so on. Although both German and Israeli authorities suspect that a fraction of those emigrating from Eastern Europe and beyond have

falsified their origins to qualify to emigrate, the overall numbers of ethnic kin, in principle, are finite. Despite the zeal shown by Israeli authorities to attract Jewish emigration from the former Soviet bloc, numbers of Jewish immigrants have declined sharply. The Israelis probably will not get the one or two million immigrants foreseen by former Prime Minister Shamir. The German government, perhaps because it bears the full cost of reintegrating the ethnic German *Aussiedler*, unlike the Israelis, has taken steps to limit the inflow. It has signed agreements with the Russian Federation to aid the reestablishment of the Volga Germans along the Volga River. It also has instituted an annual quota on the number of *Aussiedler* permitted to reintegrate into Germany.

Most aspiring migrants from Eastern Europe and beyond cannot qualify for privileged treatment on ethnic grounds. If they are to emigrate, they will need a visa or they will have to emigrate illegally. For most, visas will be difficult to come by. Illegal emigration is an option, but it is difficult and, for many, expensive. Thriving human smuggling rings have sprung up to funnel immigrants into Western Europe much as Chinese gangs do with illegal Chinese migrants to the United States. Indeed, punishment and prevention of human smuggling was one of the major goals of both the October 1991 Berlin Conference attended by twenty-seven

West and East European countries and of the February 1993 follow-up meeting in Budapest.

According to German crime statistics, more than one-half of recorded offenses for smuggling of people in 1992 were perpetrated by aliens. Parenthetically, those same statistics record 550,583 foreigners as having broken German laws in 1992. Aliens comprised one third of all suspects. While aggregate crime statistics need to be interpreted with care as they include violations of immigration laws, and while sociological factors like the relative youth and lower socio-economic status of aliens in general must be considered, alien criminality clearly also is contributing to the malaise over migration (Federal Misistry of the Interior 1993).

While human smuggling obviously will be a long-term concern, steps are being taken to stanch it. Two other factors appear to mitigate against mass unwanted migration from the East. The first is demography. International migration largely involves young adults. Much of Eastern Europe's demographic profile is not that dissimilar from Western Europe although there are exceptions like Romania.[2] One simply does not find the same demographic pressure to migrate that one finds in Egypt or Morocco, for example. Demography suggests that the threat of mass unwanted migration is much greater from the swath from Turkey to Morocco than from Eastern Europe.

Moreover, studies of illegal immigration underscore the importance of networks to illegal immigration. Networks can be comprised of family, kin, fellow villagers, or even fellow nationals who provide information about employment opportunities, offer lodging, and help aliens melt into an immigration society. In the case of the former Soviet bloc lands, they were cut off from most of the rest of the world, including Western Europe, until only a few years ago. This leads to a suspicion that networks are not in place to facilitate massive illegal migration from the East. Again the threat appears greater from the South than it does from the East because of the durable legacy of the guestworker period.

A further reason why *Voelkerwanderung* from the East has not materialized to the extent feared is proactive policy. Since 1990, Western European governments, including the European Union, have stepped up efforts to ensure that *Voelkerwanderung* does not occur. This effort is multipronged, encompassing fi-

[2] This observation was first made by Georges Tapinos, the leading French immigration expert, in a speech at the Salzburg Seminar in Austria in April 1991.

nancial and other forms of assistance, bilateral and multilateral negotiations, and other initiatives. The undeclared strategy seems to be to fashion the traditional transition zone from Eastern to Western Europe into a kind of international migration buffer zone—an illegal migration *cordon sanitaire.* Poland, Hungary, and the Czech and Slovak Republics have signed association treaties with the European Union. Their nationals will benefit from visa-free entry into the European Union (although the United Kingdom has not been cooperating on many immigration-related initiatives). The unstated *quid pro quo* is cooperation with EU member states in regulation of international migration. Specifically, readmission treaties have been signed (or prepared) that will enable states such as Germany to deport unauthorized alien entrants to the countries through which the detained illegal entrant transited.

Implementation of the readmission agreements has been difficult and incomplete, but a conceptual and legal system has been put in place that should facilitate exclusion of detected illegal residents. This has long been the achilles heel of Western European migration control strategies—a problem to which Americans should pay a great deal of attention as they reform asylum procedures. Recent reporting on bilateral Polish-German and Czech-German cooperation in control of illegal immigration suggests numerous barriers to effective cooperation remain, but progress also has been made.

All four of the buffer states have become significant immigration lands in their own right. Hundreds of thousands of Russians and others enter Poland to barter goods or to work temporarily in much the same way that Poles did in Germany in the late 1980s. Much will depend on whether these buffer states develop their governmental capacity to regulate international migration. The European Union states are encouraging them to do so through fora like the Berlin, Budapest, and Vienna conferences and more discretely by informally linking economic assistance and good relations to effective cooperation on regulation of international migration.

Another prong of proactive policy concerns steps to prevent the generation of refugees. The Treaty of Paris, to which the United States is a signatory, created the Conference on Security and Cooperation in Europe [CSCE]. The third basket of this treaty in essence envisaged the creation of a zone from the Urals to the Atlantic in which there would be minimal criteria for respect of human rights and personal welfare. If attained, the criteria theoretically would preclude *bona fide* requests for asylum by persons living in the

zone. As **Table 8** indicates, asylum applications by persons from five Central and Eastern European countries in EU member states more than doubled between 1991 and 1992. The goal of CSCE is to ensure respect for rights and maintenance of a minimal level of personal welfare so that such requests become transparently frivolous.

Alas, CSCE has not worked as hoped. The breakup of Yugoslavia has created an estimated 3.8 million refugees and displaced persons. As **Table 9** suggests, significant numbers of persons fleeing the fighting in Yugoslavia have been accorded refugee status in Western Europe, particularly in Germany. Others have been afforded temporary protected status as seen in **Table 10**. However, without wishing to appear insensitive to the suffering of others, the key lesson of the Yugoslav crisis, if it is not to premature to draw one, is that most refugees and displaced persons have not reached Western Europe, despite Trieste being a day's drive from Sarajevo. Visas are required for the refugees and displaced to get out. Most do not get them. Instead, the bulk of the victims of war and ethnic cleansing have had to find haven nearby in Croatia or UN-protected safe havens. Thus, while the Yugoslav tragedy testifies to the shortcomings of the CSCE launched with such fanfare, perhaps it also suggests what may be the pattern for the future.

Most observers agree that there is enormous potential for Yugoslav-style conflict from Bosnia to the Caucuses and throughout Soviet successor states. It is not farfetched to imagine millions and millions of additional refugees and displaced persons being created in the next decade. Like the Bosnians, many of these hypothetical refugees would undoubtedly prefer to find haven in Western Europe and other Western democracies. However, they probably will be unable to reach Western Europe and will have to find safe havens nearby. *In extremis,* confronted with an imminent mass inflow of aliens—be they refugees or not—of such magnitude as to endanger security, most West-

ern European states would conceivably use their armies to stanch unwanted entry. As a well-informed Dutch official once put it, there are three scenarios for migration from the East—bad, worse and catastrophic. Contingency planning for the latter scenario includes utilization of the military.

It is too early to declare *Voelkerwanderung* from the East a false alert. But contemplation of further variables and factors also suggest it is not going to happen in disruptive ways. Several Western European countries have authorized fairly substantial temporary foreign employment from Poland in particular. The number of Poles

officially admitted as temporary workers in agriculture and other industries in Germany has soared to between 200,000 and 300,000. Many of the new temporary foreign workers are contract workers and trainees. Many are skilled. There are some indications that Western European states are reorienting foreign labor policies to the East, particularly to Poland.

Highly-skilled and professionally-educated workers are in demand in many Western European countries despite high unemployment. Many Eastern European and Soviet successor states seek to export their labor much like East Asian states do. The Vienna Conference on East-West Migration in January 1991, which was backed by the Council of Europe, pushed the idea

of bilateral foreign labor programs. But there are no current expectations for large-scale recruitment of foreign labor from Central and Eastern Europe. Long-term labor market prospects for blue-collar workers in Western Europe are grim, despite the much ballyhooed aging of European societies within the European Union. (The total population of the European Union—347 million—is expected to fall to 340 million by 2025). The European Commission has recommended that third country nationals, e.g., Turkish residents of Germany or Algerian residents of France, be granted priority in access to employment if job vacancies occur anywhere in the EU (Commission of the European Communities 1994, p.34). As Heinz Werner has argued, and as suggested by the contrasting trends in unskilled and skilled employment of foreign workers from member states within the EU in **Table 11**, the future of labor migration belongs mainly to professional-level migrants.

All in all, the scenario of mass unwanted migration seems much more plausible for migration from the South than from the East. Demographic pressures and networks make the prospect real. Here again the worst has not yet happened. The Algerian impasse, however, is most worrisome. Already in 1990, middle-class Algerians (e.g., professors) were getting out (Talha 1990). Now millions want out and some, like Sheik Turabi in Sudan, have predicted that up to four million refugees will flee the establishment of an Islamic government. Unlike the former Socialist Minister of the Interior, who declared that France would not accept mass migration

from Algeria, the current Foreign Minister, M. Juppé, estimates that France might receive one million refugees from Algeria in the event of regime change (Eizenstat 1994).

There is a great deal of uncertainty because, under the Evian Accords that enabled Algeria's independence, Algerian citizens born before 1962 (when Algeria was legally part of France) are entitled to request French citizenship (Abdi 1994). And, the numbers of Algerian citizens requesting asylum are growing both in France and throughout the EU. In 1991, 1,730 and in 1992, 8,158 applications were made by Algerians in the EU (Commission of the European Community 1994, p.9, Annex I).

How, though, would a million Algerians flee to France? It would have to occur as a trickle, gradually, and this is happening. Some Algerian citizens with valid residency permits are returning, as are dual citizens. But as in Bosnia, most who might want to get to France cannot; they stand a better chance making it to Tunisia or Morocco. The French, and probably the Spaniards and Italians as well, will not permit a mass spontaneous arrival of tens of thousands of Algerians. They will use their militaries, if necessary, to prevent it. In the French case, in particular, one cannot ignore historical precedents. Draconian measures were taken against French citizens of Algerian Muslim origin as late as 1961 albeit in the context of the Algerian war (Einaudi 1991).

At this point, the *Fortress Europa* image might seem apt after all. But, even in this acute scenario, it is not. The French will allow entry to those entitled (the potential numbers are unclear). They will accommodate as many refugees as possible, but there is an undefined limit beyond which they will not go. Governmental handling of the Algerian impasse may damage integration goals. The arrival in power of an Islamic government would certainly complicate Franco-Algerian relations and management of transnational Franco-Algerian society. It is conceivable that fundamentalist influence would grow amongst resident aliens and citizens of North African Muslim origin, but the secularizing influence of French culture should not be underestimated. It appeals particularly to Berber minorities like the Kabyles who historically emigrated to France in dispro-portionally high numbers relative to other Algerians.

Realistically, a more frightening scenario concerning Algeria would be spillover of the violence across the Mediterranean to metropolitan France. This has not yet happened, but there is ample historical precedent. The French government al-

ready has taken steps to round up suspected Islamic militants. This cannot be said to endanger the rights of Algerian residents of France any more than it does those of French citizens. After several years of armed conflict and a steadily mounting human toll, however, a resolution to the impasse has not materialized. This casts a long shadow over the future of North Africa and Europe.

Assessing West European Capacity to Prevent Illegal Migration

Nightmare scenarios over Algeria aside, there are many reasons to expect Europe to cope with its migration dilemmas. The imagined *Fortress Europa* cannot come about short of a revolution. French Minister of the Interior Pasqua may declare that the goal of his government is zero immigration, but this represents ill-considered rhetoric, nothing more. Western Europeans realize they have a great stake in immigrant integration. Indications suggest that they will do more not less to achieve this goal in the future. Western European democracies, as **Table 12** indicates, are scarcely hermetically-sealed societies. Quite significant numbers of aliens enter legally each year. It is the illegal immigrants and asylum-seekers that most worry Europeans.

On the asylum front, virtually all Western European states have streamlined asylum procedures. Critics worry that governments have gone too far, thereby endangering respect for *nonrefoulement*. They also worry about displacement of asylum-adjudication to the fledgling democracies of Central and Eastern Europe.

Table 13 reveals a drop in overall asylum applications in 1993. A consistent pattern, however, did not emerge as asylum applications in the Netherlands, for instance, rose. Nonetheless, reforms undertaken in Germany and France in recent years clearly have had the desired effect. Apparently, asylum applications are down more than 50 percent in Germany since the revision of asylum law in July 1993 (Papademetrios 1994). Better data on the effects of recent reforms on France are available and, from the standpoint of immigration control, also are quite encouraging.

As seen in **Table 14**, asylum applications skyrocketed in France, reaching a high point of 61,422 in 1989. In 1988 and 1989, the specialized French agency for refugees —known by its acronym OFPRA—received a large budget increase. The additional monies were spent to modernize

procedures and to recruit and train additional personnel. This, in turn, enabled more decisions to be taken, and the number of decisions nearly tripled from 1989 to 1990. The average time that applications took to be adjudicated decreased to less than six months. **Table 15** indicates that the applicant recognition rate also plummeted in the late 1980s and early 1990s, although France continued to recognize a higher percentage of asylum applicants than Germany. The quickening of the average adjudication duration may have had a deterrent effect upon frivolous claims. However, roughly simultaneously, the French stopped the automatic grant of employment permits to asylum applicants.

Recent trends in asylum applications in Germany and France suggest that revisions of rules and procedures and beefing up personnel do make a difference. The change in the German asylum law will make it very difficult for applicants who transit countries abutting Germany to have their cases heard as most such individuals will be returned to the neighboring state. The Dublin Convention signed by EU member states to discourage multiple applications is not yet functioning. But, when it comes into effect, it should ease the enormous burden shouldered by Germany. The question is: Will the Austrians and the Czechs be able to cope?

Legalization policies represent another way that Western European states attempt

Table 16.

Summary of Legalizations in Selected Western European States

Austria:	Small-scale and unpublicized administrative legalizations permitted in the 1980s.
Belgium:	Overtime legalization in 1974. Government has since opposed the option.
France:	Routine legalization 1946-1968, exceptional legalization policy thereafter, 1.4 million legalizations 1948-1981, exceptional legalizations 1972-1973, 40,000; 1977-1979 (Mauricians 1,000; 1980-1981, Sentier, 3,389; 1981-1983, 150,000.
Germany:	Legalization-like policy through nominative recruitment process until 1973, small-scale, unpublicized legalizations on individual basis for humanitarian reasons thereafter,[c] officially eschews legalization policy.
Italy:	Unpublicized small-scale legalization possible until (around) 1985, on and off legalization policy in 1987 and 1988 (105,000 applicants), major legalization policy in 1990, 204,000 aliens legalized.
Netherlands:	15,000 aliens legalized in 1975, 850 legalized in 1980.
Spain:	44,000 aliens legalized in 1985-1986. Political movement in support of legalization and Spanish-Moroccan negotiations lead to limited reopening of legalization opportunity for Moroccans by 1991.
Sweden:	Several hundred aliens legalized in 1976. Government has since eschewed legalization.
Switzerland:	Legalization eschewed, but cases of excessive rigor policy grants legal status to more than 10,000 aliens, mainly asylum-seekers denied refugee status, since 1982.
United Kingdom:	Small-scale legalization 1974-1978.

to cope with illegal migration. **Table 16** summarizes the major Western European legalizations in recent years. Several states have expressly eschewed legalization. In France, "exceptional" legalizations are recurrent. The most recent one there dates from 1991 and was available to asylum applicants who had not been recognized but who could demonstrate integration into French society.

Legalization policies are attractive in that they hold out the hope of reducing the illegal alien population. However, assessment of a legalization policy's impact is difficult. There is some evidence that the French legalization of 1981 to 1983 served to attract additional illegal immigrants. French scholars disagree bitterly on how successful the legalization was. Some allege that there was widespread fraud—particularly in applications from agricultural workers—much as was witnessed in the SAW program in the United States.

Overall, the results of European legalization efforts appear mixed. They clearly did enable tens of thousands of aliens to accede to legal status—a matter of more than passing interest to the individuals and states concerned. But they were also plagued by problems and most decidedly did not resolve the illegal alien issue in one fell swoop.

Western European states also consider temporary foreign worker policies germane to their immigration control strategies. Fewer and fewer Western European officials seem to recall today that it was the guestworker idea from which so many of their current migration dilemmas arose. Few appear to remember that Western European employers and governments actively recruited foreign workers until 1973 or so.

Some scholars and officials would hold that the reverse is true, that the cause of illegal immigration is unmet employer demand and that, if only temporary foreign workers were admitted to take those jobs, much of the problem of illegal immigration would be resolved.

Whereas the debate over the wisdom of temporary foreign worker policies in Western democracies was once thought closed, the 1991 German decision to lift the 1973 blanket curb on foreign worker recruitment opens up a new chapter. Generally, however, high unemployment rates, particularly among foreign residents, discourage a resumption of large-scale foreign worker policies. Adverse political reaction to aliens also is a factor.

Table 17 chronicles the evolution of seasonal foreign worker employment in France. Retention of seasonal foreign

worker policy constituted a major exception to the recruitment curb declared in 1974 and testifies to the clout of agricultural interests in French politics. Nonetheless, seasonal worker admissions dropped steadily during the 1980s. This reflected an effort by French officials to wean growers from utilization of foreign seasonal workers. Mounting unemployment made it increasingly difficult to justify seasonal foreign worker admissions. At the same time, changes in Spain were affecting the Spanish grape pickers who used to comprise the bulk of seasonal workers. As their numbers dwindled, French growers increasingly looked to Eastern Europe, especially Poland, for new sources of labor.

Other policy instruments commonly used by Western European governments to limit illegal immigration include employer sanctions, airline carrier sanctions, more stringent visa policies, interior controls, and border controls. In a period of twenty years, most Western European states have developed panoplies of laws directed against illegal immigration and a limited, but still significant, capacity to enforce these laws. Many factors affect how well a particular Western European state fares in terms of overall deterrence of illegal immigration. The insular British, for instance, would appear to acquit themselves well without employer sanctions. The Germans, because of their geography, appear to be having a harder time. But even where illegal immigration is thought to be extensive, illegal alien employment appears concentrated in certain industries and jobs with poor wages, difficult working conditions, and work that is held in low esteem.

Off-the-books employment of Americans is not uncommon across Western Europe, but there is not much worry over it. The real worries are over the millions of unemployed and underemployed youth of North Africa, Turkey, or Rumania. Millions of them aspire to come to Western Europe, but most cannot make it. There are many hurdles in their way now that were not there in the 1950s or 1960s. Some do make it, but their existence is often quite bleak. Legalization of their status no longer appears to be either a moral imperative or advisable as Western European democracies have made it clear that they no longer intend to tolerate illegal immigration—although some refuse to believe this.

The gap between stated policies and realities may narrow in coming years despite the daunting prospects alluded to earlier. Western European governments appear to attach a high priority to international migration and they are linking immigration control aims to foreign policy,

trade, and foreign assistance initiatives. Only time will tell whether they succeed in coordinating and implementing a sustained and comprehensive approach to ameliorating their migration problem. But chances are that they will.

Implications for the United States

Regulation of international migration looms as one of the principal post-Cold War challenges to the transatlantic partners and other Western democracies. Sustained, systematic, and comprehensive bilateral and multilateral coordination and cooperation is imperative if the challenge is to be met.

Asylum policy reform, legalization policies, temporary foreign worker programs, employer sanctions, and other policies all are of broad interest, as are initiatives on the migration and development nexus. This is an area where the vision of multilateral coordination and cooperation with international agencies articulated in recent U.S. foreign policy statements can be given substance.

Western Europeans appear to desire dialogue and cooperation with the United States in this realm. In light of situations like the Algerian impasse, it would appear urgent to step up the pace of dialogue and concrete cooperation.

International migration to Europe indirectly affects U.S. national security interests. While this analysis suggests that the West Europeans will be able to cope with their migration problem, this outcome is not foreordained. As in other areas, the U.S. could play a constructive leadership role in the international migration area. Our immigration history is an important U.S. foreign policy asset and, in light of transatlantic dilemmas on migration, a multilateral resource. The key is to build a framework of predictable, sustainable, and democratically legitimate policies in the international migration area and thereby create a pillar for a return to order and comity in world affairs. Failure to accomplish this will gravely compromise any future prospects for world order. In view of the possible immensity and complexity of the international migration challenge for the United States and Western Europe, the post-Cold War challenge to transatlantic partnership can be said to be very different than that of the past, but no less vital.

Currently, Western democracies view international migration mainly as a problem. Both positive and untoward poten-

tialities inhere the phenomenon, however. Legal immigration policies express democratic will and recognition of such rights as family reunification. The legal immigration tradition of the United States is one that deserves emulation. One consequence of closer U.S.-European cooperation might well be to nudge Western Europeans towards embracing a legal immigration system that now exists *de facto.*

U.S. COMMISSION ON IMMIGRATION REFORM

MIGRATION BETWEEN MEXICO & THE UNITED STATES

ESTUDIO BINACIONAL

BINATIONAL STUDY

MÉXICO—ESTADOS UNIDOS SOBRE MIGRACIÓN

A report of the

Binational Study on Migration

ACKNOWLEDGMENTS

The Mexico/United States Binational Study on Migration was a joint effort undertaken by twenty scholars from both countries who worked together in teams on five separate subject areas and collaborated on the production of this shared report. Their efforts have produced a collective and state-of-the-art assessment of many aspects of Mexico-to-United States migration. We are appreciative of the efforts of the members who, despite their different academic disciplines and subject area expertise, worked in a productive and collegial atmosphere. This report demonstrates the commitment of the Binational members to producing a thorough and groundbreaking document.

The Binational Study was funded by both the Mexican and United States governments in conjunction with private sector funding in both countries. This structure was created to optimize the independence of the research teams and to make the final report immediately available to institutions interested in the critical role of migration in the bilateral relationship. The Mexican Ministry of Foreign Affairs contributed to and supported the work of this study. The U.S. Congress appropriated funds coordinated by the U.S. Commission on Immigration Reform, and both the U.S. Immigration and Naturalization Service and the Department of State made contributions. We also acknowledge funding received from the Consejo Nacional de Ciencia y Tecnología and the United States Information Service in Mexico. Private sector funders were very interested in the project. The Fundación Miguel Alemán in Mexico contributed and the Ford and the Hewlett Foundations in the United States also supported the entire project.

We are grateful for the data and information supplied to the Binational Study by government institutions in Mexico and the United States. We also appreciate the commissioned analyses prepared by Mexican and American consultants to the Study.

Finally, we acknowledge the many individuals in both countries who gave of their time and assisted the Study in gaining invaluable insights above and beyond the more mundane aspects of academic research. The Binational Study alternated its meeting sites between Mexico and the United States and visited several communities in both countries. Government officials were forthcoming in sharing information and hosting opportunities to learn in Mexico City, San Diego, Tijuana, Oaxaca, Washington, San Antonio, and Chicago. The members of the Binational Study especially appreciated the frank exchanges with community residents and migrants in Tijuana, Oaxaca, Guadalajara, and Chicago.

SUMMARY OF MAJOR FINDINGS I

ASSESSING MEXICO-UNITED STATES MIGRATION II

INSTITUTIONALIZING COOPERATIVE & EFFECTIVE DIALOGUE IX

GLOSSARY XI

SUMMARY OF MAJOR FINDINGS

Mexican migration to the United States is a complex and dynamic phenomenon with long historical roots. There has been migration northward since the settlement of both countries, across the frontier established in 1848, and especially from the first sizable labor migration flows during the 1870s. Today, much of the migration flow remains economically motivated by wage differences that affect supply and demand, and it is sustained by the family and social networks that connect the two countries.

The two governments have approached this northward migration with unilateral policies, as well as bilaterally negotiated programs, such as the well-known temporary agricultural "Bracero" program that existed from 1942 to 1964. Since then, the major U.S. policies affecting the flow have emanated from the Immigration Act of 1965 and the Immigration Reform and Control Act of 1986 [IRCA] that legalized some two million Mexicans in the United States under a long-term or "pre-1982 resident" program and a Special Agricultural Worker program [SAW]. IRCA also applied sanctions against employers who knowingly hired unauthorized workers. More recently, the U.S. Congress adopted the Illegal Immigration Reform and Immigrant Responsibility Act [IIRIRA] to strengthen border and worksite enforcement, facilitate removals of unauthorized aliens, and deter utilization of public programs.

This new approach occurred simultaneously with a period of heightened Mexico-United States engagement, driven in large measure by the positive bilateral relations promoted through the North American Free Trade Agreement [NAFTA]. In the last five years, there has been an upsurge of initiatives to formalize the bilateral dialogue and consultation on migration, as well as on such other issues as water management and health along the border. The Working Group on Migration and Consular Affairs of the Binational Commission has proven an important and effective forum for frank discussion of various migration issues.

This study is both a reflection and manifestation of the new spirit of cooperation. A joint undertaking by the governments of Mexico and the United States, the study's aim is to contribute to a better understanding of the nature, dimensions, and consequences of migration from Mexico to the United States. The research was conducted by a team of twenty independent researchers, ten from each country, who reviewed existing research, generated new data and analyses, and undertook site visits and consulted with migrants and local residents to gain a joint understanding of the issues raised in this study.

Assessing Mexico-United States Migration

Migration includes residents and sojourners, both legal and unauthorized. We constructed estimates of the Mexican-born population in the United States using well-known national-level data sources, with special efforts to adjust for undercounts and the number of SAW workers included. Our results suggest that the total size of the resident Mexican-born population in the United States in 1996 was within the following ranges:

Total Mexican-Born Population	7.0 - 7.3 million persons,
Legal Residents	4.7 - 4.9 million persons,
Unauthorized Residents	2.3 - 2.4 million persons.

The numbers of Mexican-born migrants represent approximately 3 percent of the overall United States population, about 40 percent of the U.S. population of Mexican-American ancestry, and are equivalent to 8 percent of the overall national population of Mexico. More than one-quarter arrived in the past five years.

About 0.5 million were naturalized U.S. citizens. In recent years, naturalization of legal Mexican-born immigrants has increased dramatically from just over 67,000 in FY 1995 to 233,000 in FY 1996. These figures for the foreign-born population are in addition to the 11 million native-born citizens of Mexican American ancestry as of 1996.

The decade of the 1980s showed a massive increase in Mexican legal immigration, largely because of the legalization program. During the 1990s, legal immigration from Mexico remained sizeable as the family members of legalized Mexicans obtained permanent resident status. In FY 1996 alone, more than 160,000 Mexicans became legal immigrants, all but about 5,300 under family-based admission categories. The future demographic consequences of IRCA could be considerable, with at least an estimated 1 million Mexican family members of legalized persons eligible to apply for U.S. admission.

Legal temporary visits between Mexico and the United States also are substantial. The border crossings between Mexico and the United States are among the busiest in the world. In FY 1996, for example, there were 280 million land crossings through the southwest border. The exact number of unauthorized entries of Mexicans into the United States is unknown, but in FY 1995 more than 1.3 million apprehensions of persons attempting to enter without inspection took place at the Mexico-United States border. These are records of events, however, and not of individuals.

Mexican census data and indirect measurement methods show that the loss of Mexican population from international migration has been systematic since 1960. According to our best estimates, the migration of persons to the United States who have established permanent residence there has been within the following ranges:

1960-1970	260,000 - 290,000
1970-1980	1,200,000 - 1,550,000
1980-1990	2,100,000 - 2,600,000

For 1990-1995, net outmigration was 1.39 million people, with essentially equal participation by gender, which is equivalent to an annual average of 277,000 for the five-year period. Our estimates based on U.S. data indicate a similar net growth in the size of the Mexican-born population from 1990 to 1996 of approximately 1.9 million persons, or about 315,000 persons per year. Breaking down the 1.9 million figure into components, we estimate that approximately 510,000 were legal immigrants, 630,000 unauthorized migrants, and 760,000 migrants who either were legalized under the SAWs program or legalized as an IRCA family member. Many of SAWs legalizations occurred in the first half of the 1990s; future flows of this type should be negligible.

The rate of back-and-forth labor movement seems to be slowing. Mexican border surveys on sojourners show a decrease in the number of persons moving in both directions between 1993 and 1995 (south-north migrants decreasing from 790,000 to 540,000 and north-south migrants decreasing from 624,000 to 433,000). This reduction in the rate of circulation can be explained by several hypotheses, the most likely of which is that many people are deciding to establish residence in the United States or to prolong their stay there. It is possible that, as the Binational Study members heard in their visits to communities in Mexico, the increasing difficulty of crossing the border has led temporary migrants to reduce the number of times they move back and forth between the two countries. New enforcement techniques have caused an increase in the number of times an individual Mexican is apprehended before making a successful entry or determining to return home. Legalization, too, may have permitted Mexican workers to bring their families, thereby reducing their need to return frequently to Mexico. Increasingly, participation of migrants in urban jobs, which are less seasonal than rural jobs, may also contribute to lengthier stays in the United States.

Characteristics vary by migrant type. We are able to approximate the characteristics of three "types" of migrants using combinations of several databases: *sojourner migrant* (legal or unauthorized whose principal residence is in Mexico); *settled resident* (legal or unauthorized who habitually reside in the U.S.); and *naturalized U.S. citizen* (who have met five-year legal residence and other requirements).

The characteristics of Mexican migrants reflect their "type," gender, the historical patterns of U.S. recruitment for Mexican labor, and the job market in which Mexicans continue to find work. For example, some 73 to 94 percent of sojourners are young men and more than one-half work in agriculture. About 55 percent of settlers are slightly older males, and about 13 percent work in agriculture. Women, who are a smaller proportion of employed migrants, tend to work in the service economy. Naturalized citizens are long-term residents and only 54 percent are males in their early forties on average and less than 10 percent work in agriculture. A greater proportion of sojourners and settlers are employed in certain sectors of construction, manufacturing, and services than are U.S. natives or naturalized Mexican-born citizens.

Clearly, the primary motive for the migrant stream is economic; however, that does not mean Mexican migrants necessarily lack jobs in Mexico. Most migrants had some kind of work in Mexico prior to migrating. Border crossing data with large numbers of unauthorized migrants find that most had work prior to leaving. Nevertheless, the majority migrated with the intention of working in the U.S., mainly to obtain higher wages.

Mexican-born migrants tend to have low skill levels, relative both to the U.S. population at large and to other migrant groups. The sectors employing Mexican-born migrants tend to seek lower-skilled workers. They also pay low wages, accounting for the low incomes and high poverty rates of Mexican-born settlers in the United States. This situation is exacerbated by the unauthorized status of many of these migrants. Less than one-tenth of sojourners complete high school, but just over one-quarter of the settlers and well over one-third of new legal immigrants and naturalized citizens do. More than one-seventh of new legal immigrants are college graduates. About one-half of the families accompanying sojourners in seasonal agriculture live in poverty while in the U.S., but their roughly U.S. $200 in weekly earnings are substantially higher than wages in Mexico for comparable work. About one-quarter of settler families live on

poverty incomes. While the average U.S. household saw income gains between 1990 and 1996, Mexican-born resident households lost income: in 1996, 11 percent of recently arrived households had incomes less than $5,000, whereas in 1990, about 5.5 percent had such low incomes. Unauthorized status is a factor, the annual earnings of legal immigrants in 1996 was more than $19,000.

Despite much continuity in origins and characteristics, migration shows increased diversity over time. Traditionally, migrants have been rural males from a subset of communities in the west central states of Jalisco, Michoacán, and Guanajuato. The new diversity shows up in changing demography, origins and destinations, and labor force characteristics. Today, Mexican migrants appear to be older, have more education, more are women, and more are coming from "new sending" states and urban areas. In the United States, Mexican migrants are highly concentrated in California, Texas, and Illinois: about 85 percent of all Mexican-born immigrants resided in these three states compared to 45 percent of all immigrants to the U.S. in 1990. At the same time, Mexican-born migrants have become attracted to new geographic destinations. Midwestern, southern and eastern states that have had few Mexican-born workers now are destinations for Mexican-born persons employed in agriculture and food processing, construction, manufacturing, and low-skill service occupations.

The demand of United States employers and the economic motivation of Mexican migrants is sustained by network and supply factors. The catalyst for much of unauthorized Mexican migration is better-paying U.S. employment, but over time new factors have created a larger and more complex set of reasons that sustain the flow. Migration is a dynamic process and the factors that drive it change. Today new employers and labor brokers, along with cross-border social networks of relatives and friends, link an expanding list of U.S. industries, occupations, and areas to a lengthening list of Mexican communities that send migrants to the U.S. Push factors that increase the supply of labor seem to have become more important since the mid-1980s as a result of recurring Mexican economic crises and Mexican policies, such as the restructuring of rural Mexico that made small-scale farming less attractive. This means that Mexicans migrate to the U.S. within well-established networks, as well as through new networks that are developing to move migrants to the U.S. from regions without a tradition of migration. One of IRCA's effects was to strengthen such networks and to transform a portion of the flow from sojourner to settler.

Demographic and economic factors may reduce future migration. There is reason to believe that currently high levels of migration may represent a "hump" or peak in the volume of Mexico-United States migration. In the U.S., American employers are adjusting to higher minimum wages, to greater global competition, and to a likely increased supply of low-skilled U.S. residents shifted out of welfare programs. In the past, employers have adjusted to higher wages and increased competition by switching to means of production that lessen their reliance on low-skilled labor. All of these factors may decrease the availability of jobs for some types of Mexican migrants.

Within the next decade, changes in Mexican demographics and other structural changes should begin to reduce emigration pressures. Net increases in the labor forced aged 15 to 44, which was between 500,000 and 550,000 in 1996, is projected to decrease to 430,000 in 2010. Mexico has adopted an ambitious restructuring and privatization program in the 1990s that promises to increase economic efficiency and job growth in the medium- to long-term. The International Monetary Fund and Mexico's 1997 development plan both project 5 percent annual economic growth that, if achieved, would soon create sufficient new jobs to match or exceed the growth of the labor force. Analyses done for this study show that even a more modest 3 percent rate of growth could generate just under 800,000 new jobs annually by 2005. Sustained job growth can help Mexico catch up on job creation for currently unemployed and underemployed workers, those displaced from agriculture and other industries, and nonworking women who rejoin the labor force. These changes in Mexico may reduce supply-side pressure, while the changes in the U.S. may lessen the demand for Mexican workers.

Migration has varied effects, producing both benefits and costs. It is difficult to establish a balanced evaluation of migration's impacts because of the lack of data and the need for focused research in both countries. We caution against overly simplistic conclusions about costs and benefits and note that the perspectives on the balance differ in each country. In Mexico, those who return most often are the sojourners, many of whom benefit from their U.S. experience. In the U.S., the settler population—often older and sometimes unauthorized, but increasingly with legal status—has relatively low skills that place it at a disadvantage relative to other U.S. residents in an "information age" economy. At the national level, economic impacts are diffuse in both Mexico and the United States. However, strong impacts are found at local and regional levels.

Remittances play an important role in many Mexican communities, but migration creates costs due to the loss of human capital and social disruption. The most important direct impact of migration is the income sent home to Mexico by migrants in the United States. Remittances were equivalent to 57 percent of the foreign exchange available through foreign direct investment in 1995, and 5 percent of the total income supplied by exports. In Mexico, the impacts are concentrated in about 100 municipalities in the west central and northern regions of the country. The average remittances received by migrants' families are equivalent to the household's other earnings. Remittances have financed some productive investments, as well as housing and urban development. Although the direct beneficiaries are households that receive remittances, markets spread some effects to other households and businesses.

Remittances vary widely among migrants depending on their U.S. earnings and the cost of trips back-and-forth. Most migrant earnings do not accrue directly into Mexico's economy as they are spent in the U.S. Migration represents some loss of human capital for Mexico as migrants are mostly a working-age population with education and good health. Other adverse effects in Mexico include the social disruptions that affect the outmigrants' families and communities.

Migrants themselves, businesses, and consumers benefit most in the United States, with costs incurred by state and local governments and low-skilled workers. The primary beneficiaries of Mexico-to-United States migration are the migrants themselves and the U.S. owners of capital and some agricultural land, as well as American consumers and the American economy that grows through the employment and the consumption generated by Mexican migration. In the labor market, the costs associated with the migration are primarily to labor "substitutes," i.e., new Mexican migrants compete primarily with other low-skilled workers, especially already resident Mexican migrants.

On the fiscal side, Mexican migrants were not more prone to use welfare than similar natives. A statistical analysis of 1990 Census data finds that, *compared to similar native* households, Mexican-born households with young heads are *less* likely to obtain means-tested benefits. By contrast, those with heads older than 65 years are *more* likely to receive assistance, probably Supplementary Security Income [SSI]. Sojourners and recent migrants pay some taxes yet rely little on government services because they are young and, oftentimes, their unautho-

rized status makes them ineligible. However, research on settlers finds that many state and local governments pay more in services to Mexican-born households than they receive in taxes, largely because their lower incomes result in lower taxes paid. The single largest fiscal cost is related to education, which can be seen both as a public expenditure and as an investment in the future.

The Mexican-origin population is projected to be of increasing importance early in the next century. Because of the combination of migration and higher than average fertility rates, the proportion of the U.S. population that is of Mexican origin will grow. Low past rates of naturalization and of voter turnout, coupled with voting districts apportioned according to Hispanic population totals that have few eligible and voting-age persons, have weakened the potential impact of the Mexican migration in the U.S. political system. This could change. In some cases, Mexican-Americans have helped rebuild decaying inner-city neighborhoods.

Border relations are largely positive, although tensions do erupt. Migration within the border area is a special case because of the strong family, commercial, and social connections of the residents of many neighboring communities. The vast majority of border crossers go for short visits, often purchasing goods on the other side of the border. The contributions to local economies on both sides of the border that emanate from this cross-border commerce are substantial. Nevertheless, some byproducts of cross-border migration, including petty crime, vandalism, vice, violence, and uncompensated use of health care and other services, can create tensions.

Violence and human rights abuses of unauthorized migrants are major sources of concern. Unauthorized migrants are sometimes victims of crimes—from attacks and abandonment by smugglers to theft, rape, and even murder—and suffer the physical consequences of difficult border crossings. Human rights abuses by federal, state, and local officials have been recorded, which is a matter of great concern for both countries. Officials in both countries have been attacked by smugglers as well. Both governments have taken action to curb these various abuses but border violence continues to be a source of tension.

Policymaking has been episodic in nature. The political responses of Mexico and the United States to migration have an episodic character; the debate on migration is greatly influenced by the changing economic conditions in

both countries. Policymaking also has been reactive with the action of one country leading to the reaction of the other. The pace of the reactive process has accelerated in recent years. Often the U.S. has acted unilaterally. And due to the influence of various interest groups, migration policy at many times has been contradictory and yielded unexpected results. There may be many unanticipated impacts for resident—authorized and unauthorized—populations in the wake of a trilogy of legislation passed in the United States in 1996 (on immigration, terrorism/crime, and welfare).

The Mexican government has shifted from a position of deliberate nonengagement on migration matters, based on the principle of noninterference in the internal affairs of other countries, to a stance of increasing dialogue with U.S. counterparts to better address migration issues. The Mexican government also has developed a presence in Mexican communities in United States. In addition, diplomatic and consular protection activities and cultural and business promotion, have increased. The North American Free Trade Agreement [NAFTA] signed in 1993 did not contain major policy on migration; nevertheless, it created new institutional arrangements facilitating political and economic contacts and breathed new life into consultative groups. These developments are of major consequence for the bilateral relationship. However, with the policy of opening the border for commerce and investment but not for people, the potential for bilateral tension remains.

Institutionalizing Cooperative & Effective Dialogue

The study findings argue for increased dialogue and forward-looking consultative mechanisms to facilitate bilateral cooperation in finding mutually beneficial solutions to unauthorized migration between Mexico and the United States. The Working Group on Migration and Consular Affairs of the Binational Commission has been an effective platform for frank discussions on migration issues. However, the Working Group's efforts could be supplemented and enhanced with frequent discussion around an agenda of issues that would be informed by the best possible empirical and policy analyses. At a minimum, the framework for discussion must acknowledge that no single approach will address adequately the issue of unauthorized migration. Demand, supply, and networks all contribute to these movements, and, thus, solutions must be multifaceted and found in both countries. And there must be a careful approach to migration problems that is sensitive to differences in perspectives and build on the joint Mexican-United States commitment to foster human rights.

More specifically, the following issues should be on the agenda for joint discussion:

Outcomes of 1996 Legislation. The U.S. adopted a trio of laws affecting migration, including the Illegal Immigration Reform and Immigrant Responsibility Act, the Antiterrorism and Effective Death Penalty Act, and the Personal Responsibility and Work Opportunity Reconciliation Act, while Mexico adopted a Constitutional amendment that will allow dual nationality for Mexicans who naturalize. Regular, joint monitoring could help identify the intended and unintended results of newly enacted legislation in a more timely fashion.

Migration Impact Statements. One way of bringing these issues to discussion would be to formalize them as "impact statements" along the lines of the suggestion in 1990 by the U.S. Commission for the Study of International Migration and Cooperative Economic Development. These impact statements should assess direct changes in immigration policy as well as changes in economic and other policies that may affect migration patterns.

Addressing the Demand, Supply, and Network Factors. On the top of any rolling agenda list should be unauthorized migration that both countries have an express interest in addressing. The governments should assess the effectiveness of strategies to reduce employer demand for unauthorized workers, to provide increased economic opportunities within Mexico, and to reduce the efficacy of formal and informal networks that now link the supply of unauthorized labor in Mexico with U.S. demand for such labor.

Facilitating Legal Movements between Mexico and the United States. Economic and social integration means increased need to accomodate, and even to facilitate, mobility of persons between the two countries. Mexico and the United States should engage in systematic analysis of policies that will support trade, investment, and commerce by facilitating legal movements and easing barriers to legal entry.

Continued Bilateral Research and Data Collection. The development of a binational policy agenda would be greatly enhanced, as we have learned from the Mexico-United States Binational Study, with the use and analysis of data from both nations. The dynamic process of migration, also documented in this study, calls for building capacity and infrastructure to assess migration's nature, effects, and responses.

Maximizing Benefits and Minimizing Costs. It is to the clear benefit of both countries to work towards eliminating unauthorized migration, which creates costs for both countries and makes migrants vulnerable to exploitation. That process should be helped over the long-term by demographic and potential economic trends in Mexico and the United States. In the interim, the two countries should explore ways to capitalize on the economic return to migration (for example, by reducing the cost of transferring remittances and helping families use them towards productive purposes) in order to stimulate economic development in Mexico. Further, ways to enhance labor standards in the United States should be explored to reduce the incentives to employers for hiring unauthorized workers.

A "Guestworker" Program is unlikely to be a Solution to Unauthorized Migration. The United States and Mexico should study carefully the concept of a bilateral foreign worker program, recognizing that such a program is unlikely to be an effective remedy to unauthorized migration or to have sufficient labor standards to protect the rights of workers. A guestworker program could stimulate new migration networks, adding to, rather than substituting for, unauthorized workers. Continued outflow of workers also might make investors reluctant to invest in emigration areas.

Recognizing and Addressing Social Costs of Migration. Mexican migration has social costs, particularly the separation and breakup of families. Attention should be given to ways to alleviate the disruption to families and communities. For example, the two governments could explore ways to identify and obtain support for families, mostly female-headed, who have been deserted by migrating husbands/fathers.

Glossary

Immigrant. A person who migrates over international-boundaries into a country of which he or she is not a citizen. In the United States, the legal-technical meaning of "immigrant" is restricted to persons admitted for legal permanent residence. Because international migrants from Mexico sometimes are not legally admitted or are not permanent residents, the text often refers simply to migrants.

Legal Status in the United States. There are several major legal status categories (Mexico has a parallel division of legal status as well):

> **Unauthorized Migrant.** Person who has entered without inspection [EWI] or overstayed his or her U.S. legal temporary visa. Also a person who works without authorization, regardless of mode of entry. Commonly referred to as "undocumented" or "illegal alien."

Legal Nonimmigrant [NIV]. Person admitted into the United States legally on a temporary visa for a temporary stay for tourism, study, or work.

Legal Permanent Resident [LPR]. Most Mexican-born settlers are LPRs and are predominantly sponsored in the family reunification categories of the U.S. admission system.

Legalized Resident. The Immigration Reform and Control Act of 1986 granted a one-time amnesty to formerly illegal residents who, after one year, become LPR-eligible (DOL 1996:87).

Pre-1982 Residents [245A]. 1.09 million Mexican-born were legalized under this program that required continuous five-year residency at the time of application.

Special Agricultural Workers [SAW]. 877,000 Mexican-born were legalized with the requirement that they had worked at least ninety days in agriculture in the preceding three years.

Naturalized Citizen. Legal permanent residents must wait five years and meet certain qualifications before becoming "naturalized citizens" with the full voting and societal rights of the native-born citizenry (born on U.S. soil).

Mexican-Born. Persons born in Mexico and, with few exceptions, originally nationals of Mexico at birth.

Mexican-Origin. Residents in the United States, who are Mexican or native born of Mexican ancestry. Includes Mexican Americans.

Migrant Types. Persons vary in the time they spend abroad and/or their purpose for migration. Of the many different patterns that exist, we distinguish two broad ones:

Sojourner. Includes many different types whose primary residence is in Mexico, the largest subgroup may well be "circular" or "target" migrants who work in the United States for short periods.

Settler. Encompasses both unauthorized and legal permanent residents of the United States whose primary residence is in the United States.

Networks. The social connections between people that provide information and, often, a way of facilitating migration northward. For example, a "migrant network" might link an aspiring migrant in Oaxaca with a friend or relative in Los Angeles, from whom the aspiring migrant can learn of job and housing possibilities.

Remittances. Monies sent by migrants abroad back to their families or friends in their country of origin.

Stock and Flow. Migration is measured either as a "stock," or persons who reside in a place, or "flow," persons who have moved in or out of a place within a given period.

Supply and Demand. Employers need workers or, as economists say, they demand labor. The supply of labor refers to the number of workers with certain characteristics from whom the employer can choose. Just how many workers employers "demand" or how many workers are "supplied" depends on the wage employers offer and the wage that workers will accept.

MIGRATION BETWEEN MEXICO & THE UNITED STATES

ESTUDIO BINACIONAL

BINATIONAL STUDY

MÉXICO—ESTADOS UNIDOS SOBRE MIGRACIÓN

A report of the

Binational Study on Migration

ACKNOWLEDGMENTS

The Mexico/United States Binational Study on Migration was a joint effort undertaken by twenty scholars from both countries who worked together in teams on five separate subject areas and collaborated on the production of this shared report. Their efforts have produced a collective and state-of-the-art assessment of many aspects of Mexico-to-United States migration. We are appreciative of the efforts of the members who, despite their different academic disciplines and subject area expertise, worked in a productive and collegial atmosphere. This report demonstrates the commitment of the Binational members to producing a thorough and groundbreaking document.

The Binational Study was funded by both the Mexican and United States governments in conjunction with private sector funding in both countries. This structure was created to optimize the independence of the research teams and to make the final report immediately available to institutions interested in the critical role of migration in the bilateral relationship. The Mexican Ministry of Foreign Affairs contributed to and supported the work of this study. The U.S. Congress appropriated funds coordinated by the U.S. Commission on Immigration Reform, and both the U.S. Immigration and Naturalization Service and the Department of State made contributions. We also acknowledge funding received from the Consejo Nacional de Ciencia y Tecnología and the United States Information Service in Mexico. Private sector funders were very interested in the project. The Fundación Miguel Alemán in Mexico contributed and the Ford and the Hewlett Foundations in the United States also supported the entire project.

We are grateful for the data and information supplied to the Binational Study by government institutions in Mexico and the United States. We also appreciate the commissioned analyses prepared by Mexican and American consultants to the Study.

Finally, we acknowledge the many individuals in both countries who gave of their time and assisted the Study in gaining invaluable insights above and beyond the more mundane aspects of academic research. The Binational Study alternated its meeting sites between Mexico and the United States and visited several communities in both countries. Government officials were forthcoming in sharing information and hosting opportunities to learn in Mexico City, San Diego, Tijuana, Oaxaca, Washington, San Antonio, and Chicago. The members of the Binational Study especially appreciated the frank exchanges with community residents and migrants in Tijuana, Oaxaca, Guadalajara, and Chicago.

I. INTRODUCTION

Few issues hold greater implications for bilateral relations between Mexico and the United States than does migration. As a member of this team recently wrote, "the tension created by migration from Mexico to the United States is perhaps the most intractable theme in the relationship between the two neighbors, one highly developed, the other less developed. At times, the friction between the two countries over this issue is modest and, at others, incandescent, but it is never absent" (Weintraub 1997:284).

Migration from Mexico to the United States is more than one hundred years old. This history is replete with efforts by one or both countries to regulate the movements northward. Sharing one of the longest land borders between two countries with disparate earnings and income levels, Mexico and the United States have found many ways to address migration concerns. Table I-1 gives a brief summary of policies in the major historical periods of Mexican migration to the United States.

Over the years, when labor shortages have grown as a result of war or other factors, unilateral recruitment and such bilateral agreements as the Bracero Program have resulted in large-scale movements of Mexican workers into the United States. When economic conditions have reduced the need for additional labor, created anxieties among U.S. workers, or made it difficult for migrants to find work, large-scale repatriation has occurred, sometimes by U.S. government action and with Mexican government assistance to returnees.

During the past two decades, unauthorized migration between the two countries has tended to dominate the policy agenda on Mexico to United States migration (Bean et al. 1997). Through much of the period from 1975 to 1986, U.S. authorities debated what would be the best approach to reduce unauthorized migration. Eventually, in 1986, Congress passed IRCA, which adopted a variation of the grand compromise that had been advanced by such bodies as the congressionally-mandated Select Commission on Immigration and Refugee Policy: employer sanctions and mass legalization. Because the largest national group in the unauthorized immigrant population was from Mexico, both of these provisions were seen as having a major impact on Mexicans.

IRCA had significant intended and unintended consequences for Mexico to United States migration. The size of the Mexican population in the United States increased dramatically during the late 1980s and early 1990s due to IRCA's legalization provisions. Starting in 1987, about 1.7 million long-term unauthorized migrants and an additional 1.3 million unauthorized Special Agricultural Workers [SAWs] applied for legalization under the amnesty provisions of IRCA.

Table I-1. Major Historical Periods in Mexico-to-United States Migration

1870-1890	U.S. recruitment for southwestern rails and agriculture, Mexican Consular Law of 1871 provides for protection of Mexicans abroad with respect for local sovereignty;
1891-1917	U.S. laws restrict Mexican (and Canadian) land admissions, U.S. World War I recruitment (including some Canadians and Bahamians), Mexican Consular report of salary abuses of Mexican workers in U.S. (Gomez Arnau 1991);
1920s	U.S. Border Patrol established, undocumented entry considered a misdemeanor with penalties attached, and exclusions of Mexicans on "public charge provisions" are common;
1929-1933	U.S. Depression-times repatriation of Mexicans partly funded by Mexican and private aid groups with frequent promotion by Mexican consulates (Gamio 1930);
1940s	World War II era Bracero agricultural workers program begun, jointly negotiated by both governments (also a smaller railroad program from 1943-1946);
1951-1952	Upon third renewal of Bracero program, Mexico suggests U.S. measures against the employment of unauthorized workers, but U.S. adopts "Texas Proviso" making it a felony to import "illegal aliens" while exempting employers from culpability (García y Griego 1981);
1954	Negotiations for a new Bracero agreement break down though U.S. continues recruitment, Mexican government attempts unsuccessfully to stop outmigration, massive U.S. deportations of unauthorized workers under "Operation Wetback;"
1964	Termination of the Bracero program;
1980s	U.S. Immigration Reform and Control Act of 1986 [IRCA] imposes sanctions on employers who knowingly hire unauthorized workers and legalizes two million unauthorized residents, U.S. Asencio Commission recommends economic development to address unauthorized flow, Mexico reinforces and expands its consular protection of Mexicans abroad;
1990s	Bilateral dialogue on migration increases, North American Free Trade Agreement [NAFTA] signed, U.S. strengthens border control, new U.S. laws expedite removal of unauthorized migrants and restrict welfare benefits to legal immigrants, the Mexico/U.S. Binational Study on Migration is established.

Most of these persons had already been in the U.S.; during the 1990s, their close family members began to obtain legal status in sizeable numbers. INS reports that nearly 1.6 million Mexicans were admitted as legal U.S. residents between 1981 and 1990; an additional 1.5 million were admitted in Fiscal Years 1991 - 1995. Beginning in 1995, the number of Mexican immigrants becoming citizens also increased substantially, at least in part because those legalizing their status under IRCA became eligible for naturalization.

At the same time, unauthorized migration continued, pointing to weaknesses in IRCA's enforcement approach. A proliferation of fraudulent documents permitted unauthorized workers to obtain jobs despite the requirement that employers check the employment authorization of new hires. After an initial decline in border apprehensions, the number of apprehended migrants began to climb and returned to almost pre-IRCA levels, with 1.3 million apprehensions in 1995.

The continuing unauthorized entries, not only of Mexicans, but also other nationalities, led to passage of the Illegal Immigration Reform and Immigrant Responsibility Act [IIRIRA] of 1996. Building in part on IRCA's provisions, the new legislation augmented border controls, required new pilot programs to test more secure forms of employment verification, clarified eligibility for public benefit programs, bars unauthorized residents for three or ten years from legal admission, and made sweeping changes in provisions for the removal of unauthorized migrants. In conjunction with two other new laws—the Antiterrorism and Effective Death Penalty Act of 1996 [AEDPA] and the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 [Welfare Reform Act]—IIRIRA represents a new phase in recurrent efforts by the U.S. government to address migration issues.

The last two decades also brought different measures on the part of Mexico. Some were internal, such as the border-industry or Maquiladora Program that was intended to absorb workers returning from the Bracero program. Yet, most measures were directed to strengthen and broaden the consular protection of Mexicans in the United States. More Mexican consular offices have been opened in the United States, mobile consulates reach out to Mexicans outside of the major cities, and more personnel have been dedicated to the protection of Mexican nationals. Consular officers have increased their visits to U.S. worksites and Migrant Detention Centers. Hospitals and jails are likewise included in regular visits. These visits provide an opportunity for consular officers to assist migrants in their relations with U.S. authorities and nationals, to advise migrants on U.S. laws, to help recover unpaid salaries or solve other labor-related problems, and to assist migrants to contact their relatives in Mexico or the U.S.

Despite the continuity reflected in these legislative initiatives and protection policies, the overall context for addressing migration issues between the two countries has shifted markedly. The 1990s brought closer relations and a cooperative economic relationship after the 1993 approval of the North American Free Trade Agreement [NAFTA] between Mexico, the United States, and Canada. NAFTA alone will not solve the problems of unauthorized migration although increased trade and economic development continue to pose the best hope for reducing migration pressure in the long run.

The two governments are engaged, as never before, in working together to solve common problems. Binational working groups meet regularly to coordinate and cooperate on issues ranging from facilitating border crossing to antismuggling initiatives. A further measure of these new arrangements can be seen in new responses. In contrast to earlier periods, when the U.S. acted unilaterally and Mexico was largely silent regarding U.S. legislation, both governments promote dialogue through various bilateral groups and mechanisms, including the summit meeting between Presidents Zedillo and Clinton in May 1997.

This study itself derives from the new spirit of cooperation. After a meeting of the Migration and Consular Affairs Group of the Mexican-United States Binational Commission in March 1994, the governments of Mexico and the United States agreed to undertake a joint study of migration between the two countries. The main objective of the Mexico/United States Binational Study (1995-1997) is to contribute to a better understanding and appreciation of the nature, dimensions, and consequences of migration from Mexico to the United States. It also provides an opportunity to identify options to respond to these movements.

This study is the joint effort of a team of twenty researchers, ten from each country. They have worked in five subgroups focusing on distinct elements of the migration phenomenon: quantification of the scale of migration between Mexico and the United States; characteristics of the migrants; the factors that cause, sustain, or hinder migration; the impacts on the two countries; and the responses adopted individually or jointly by Mexico and the United States. The study team reviewed existing research conducted on migration between Mexico and the United States, and it generated new data and analysis conducted by team members and outside consultants to the project. The research team also undertook site visits to Mexican and U.S. communities experiencing the effects of migration in order to gain a joint understanding of the issues raised in this study.

II. THE MEXICAN-BORN POPULATION IN THE UNITED STATES

In both Mexico and the United States, questions about both the numbers of migrants from each country residing in the other (the "stock" of migrants) and the size of the migration streams crossing the border (the "flow" of migrants) arise frequently in public debates about migration. Moreover, analyses of the causes and impacts of migration in both countries depend, to a considerable extent, on calculations about the size of the stocks and flows of migration within and between both countries. In assessing and developing estimates of the stocks and flows of migrants between the two countries during the mid-1990s, we build on the approaches and results of earlier assessments as well as on newly available data and research conducted in the 1990s.

Methodology & Data Sources

The stock of Mexican-born persons refers to the number who have ever come to the United States who reside in the U.S. at any given point in time. The flow refers to the number coming in only within a given period of time, usually expressed as a net figure by subtracting the number leaving within the same period from the number coming in. In developing estimates of stocks and flows, this study bases its conclusions on data collected in both Mexico and the United States. As a result, our confidence in the estimates is considerably enhanced because we are able to assess consistency by comparing information from each country.

Mexican Data Sources. The study uses a variety of Mexican data sources. Since the late 1970s, Mexico has carried out various household sample surveys with the goal of directly quantifying how many migrants move to the United States. The 1992 ENADID (National Survey on Demographic Dynamics), the most up-to-date survey developed by INEGI, provides a basis for classifying Mexican residents (who at the time of the interview were living in Mexico) as either sojourners (people who had been in the United States to work but had not intended to stay) or as return migrants (people who had gone to the U.S. to establish residence but eventually returned), or both. This survey also provides estimates of the number of Mexican emigrants who established their residence in the U.S. between 1988 and 1992 and still live there. Other surveys, like EMIF (Survey of Migration to the Northern Border) developed by CONAPO (National Council on Population), COLEF (College of the Northern Border), and the Ministry of Labor, provide additional data to measure the number of persons involved in circular migration. Because direct survey measures of migration to the United States are based on data such as these that are difficult to collect, researchers also apply indirect demographic methodologies to Mexican census data to estimate migration stocks and flows.

United States Data Sources. The study also utilizes a combination of United States data sources, including the U.S. Census, the Current Population Survey, and administrative data from the Immigration and Naturalization Service. We develop new information on the survey undercounts of migrants and immigrants and on the relative inclusion of newly-legalized workers to get a balanced sense of the most probable range of legal and unauthorized persons. Rigorous analytic approaches are necessary because, as is well known, early efforts to determine the size of the total unauthorized migrant population produced results that were highly speculative and ranged widely (Bean et al. 1990). Unfortunately, this can be misleading for decisionmakers. Several kinds of estimation difficulties are addressed separately in the cases of the legal and unauthorized populations to reach the soundest possible estimates of these Mexican-born populations in the United States.

Migrant Types: Sojourner Settler & Citizen

In estimating numbers, or discussing characteristics and impacts, it is not possible to talk of a "homogenous" Mexican-born population in the United States. It is highly diverse, varying in terms of permanence of residence, legal status, and education and skills. It is made up of persons who stay from only a few hours to a few days to a few years, to those who reside permanently. It also includes persons with different legal statuses: (1) legal temporary visitors; (2) legal permanent residents, otherwise known as legal immigrants; (3) naturalized United States citizens; and (4) unauthorized migrants, including individuals who enter without permission, through the use of fraudulent documents, or with permission but who violate the terms of their visas. Legal status shapes the environment in which the migrant makes decisions when searching for a job, deciding where to live, and investing in schooling and English language skills. These legal status groups are often dissimilar; yet, occupational backgrounds as different as agricultural worker or skilled operator may be found within any given legal status.

Two major migration patterns, apart from legal status, can be found in the data to distinguish migrants. Sojourners may remain in the United States for anywhere from hours to months but consider Mexico to be their place of principal residence and are mostly "circular" migrants who work short periods in the U.S. (other subtypes of sojourners may include short-term visitor such as shopper, visitor, businessperson, temporary-resident worker, student, family member, vacationer). Settlers consider the U.S. to be their permanent residence even if they return to Mexico for short visits (also known as long-term residents) (Chavez 1988). Mexican-origin persons are found in all combinations of the four

legal statuses and the two migrant patterns. For example, sojourners include unauthorized migrants, legal temporary workers, students (nonimmigrants), persons who become legal permanent residents, and even naturalized citizens. And individuals within a household may differ by legal and migration status, as well as move across legal-status and migration-patterns over their life.

Population Estimates

Our estimates are presented first for the stock of Mexican-born population in the United States and then for the flow of Mexicans northward, with distinctions made where possible among the various types of migrants.

Estimates of Stock. *Our results indicate that the total size of Mexican-born resident population in the United States in 1996 (both enumerated and unenumerated, legal and unauthorized) was 7.0 - 7.3 million persons. Of this population, legal residents accounted for about 4.7 - 4.9 million persons, about 0.5 million of whom were naturalized United States citizens. Unauthorized migrants accounted for 2.3 - 2.4 million persons* (Bean et al. 1997). These estimates are derived from a combination of Mexican and United States data sources. We emphasize that these are estimates. The U.S. Census and other surveys, such as the CPS, do not ask residents about their legal status. However, because the total population is known, and because it is possible to estimate legal residents, residual methods provide an estimate of the part of the unauthorized population that is enumerated (i.e., unauthorized = [total foreign born] - [legal residents]). Each of the components of the residual equation may be too low, primarily because a subpopulation is undercounted or "underenumerated" due to the practical problem of finding all countable persons with survey methods. To address this in our estimates of these populations, we undertook demographic investigations to find plausible levels of undercount. We also addressed the likely number of newly-legalized Special Agricultural Worker [SAW] immigrants in the United States as of 1996, a rather substantial issue in making residual estimates.

Table II-1. Total Mexican-Born Population in the United States: 1996

Total (in millions)	7.0 - 7.3
Legal Permanent Residents	4.7 - 4.9
Unauthorized Migrants	2.3 - 2.4

The Flow of Migrants Northward. *Mexican migration to the United States has increased notably since the decade of the 1960s, and it has continued to grow significantly in recent years.*

Direct measures based on Mexican data indicate that 2.6 million persons living in Mexico as of 1992 had migrated to the United States sometime in the past—1.0 million migrated just to work, 1.3 million migrated to work and settle, and 0.3 million migrated to take up residence but not to work. Between 1988 and 1992, 1.1 million Mexicans migrated to the United States, but by 1992 had returned to live in Mexico—250,000 had migrated just to work, 707,000 to work and settle, and 140,000 to settle only. At the same time, another 1.0 million Mexicans entered the United States and were still resident in the U.S. in 1992—their numbers represent a lower limit of the net flow of Mexican migrants during the period.[1]

Estimates from indirect measures using census data from Mexico indicate that the loss of Mexican population from international migration has been systematic since 1960 and that the estimated size of the flow during the past decade was substantial and lowered Mexico's rate of population growth (Corona & Tuirán 1996a).

Table II-2. Growth in Permanent Mexican Migration to the United States

	Migrants Who Have Established United States Residence
1960-1970	260,000 - 290,000
1970-1980	1,200,000 - 1,550,000
1980-1990	2,100,000 - 2,600,000

During 1990-1995, total net outmigration was 1.39 million people, with roughly equal shares comprised of males and females, and equivalent to an annual average of 277,000 for the five-year period. This estimate is substantially higher than that observed during the decade 1980-1990. The estimates based on U.S. data (from the 1990 U.S. Census and 1996 U.S. Current Population Survey) indicate a net growth in the size of the Mexican-born population from 1990 to 1996 of approximately 1.9 million persons, or about 315,000 persons per year, a figure somewhat above the figure based on Mexican data. (The U.S. figure is higher because U.S. data sources include both some sojourners and settlers.) Breaking down the 1.9 million net figure into components, we estimate that approximately 510,000 are legal immigrants, 630,000 are unauthorized immi-

grants, 210,000 are IRCA family members, and 550,000 are migrants who had legalized under the SAW program.

Subdividing these figures into net annual flows can be misleading because on a yearly basis some flows are so uneven. For example, many of the SAWs probably came in the early 1990s; future flows of this type should be negligible, because of the termination of the SAWs program nearly a decade ago.

In addition to these numbers, data from the EMIF indicate that the number of Mexican sojourner migrants involved in the circular flow (those who live in Mexico and travel periodically to the U.S. to work or look for work) appears to have declined in recent years: the south-north flow (i.e., from Mexico to the U.S.) decreased from 792,000 in 1993 to 543,000 in 1995, and the north-south flow (i.e., from the U.S. to Mexico) also decreased from 624,000 to 433,000 during the same years. This reduction can be explained by any of the following three hypotheses: (1) a growing number of sojourners have decided to establish residence in the U.S. or decided to prolong their stay there; (2) an increasing number of migrants decided to remain in Mexico instead of travelling periodically to the U.S.; (3) a combination of the two previously-mentioned possibilities, although with specific weights yet to be determined by research. The observed increase in the estimated size of the net flow of permanent residents in the U.S. during those years, associated with both unauthorized immigrants and legalized immigrants under the SAWs program, suggest that the reduction in the magnitude of the flow of circular migration is mainly explained by the first hypothesis suggested above.

Other Issues & Trends

Legal Permanent Immigration. *An upward trend in legal immigration to the United States and, in the case of Mexico, the additional impact of IRCA's amnesty programs, resulted in an increasing presence of legal residents.* The decade of the 1980s showed a massive increase in Mexican legal immigration, largely because of the amnesty program. During the 1990s, legal immigration from Mexico remained sizeable as the family members of legalized Mexicans obtained permanent resident status. Table II-3 presents INS data showing the number of Mexicans admitted with legal permanent resident status. In FY 1996 alone, about 160,000 Mexicans became legal immigrants, all but about 5,300 under family-based admission categories. Many of the legal immigrants are believed already to have been living in the United States at the time they gained legal status.

Table II-3. United States Legal Admissions: FY 1996

CATEGORY	ALL IMMIGRANTS	MEXICAN-BORN IMMIGRANTS	MEXICAN PERCENT OF ALL IMMIGRANTS	PERCENT OF MEXICAN IMMIGRANTS IN CATEGORY
FAMILY-BASED	593,692	154,400	26.0	96.7
Immediate relatives	299,941	55,400	18.5	34.7
Preference visas	293,751	99,000	33.7	62.0
EMPLOYMENT-BASED	117,300	3,501	3.0	2.2
OTHER	198,927	1,830	0.1	1.1
TOTAL	909,959	159,731	17.6	100.0

Source: Public use admission data, U.S. Immigration and Naturalization Service.

The exact level of net legal immigration has been difficult to pinpoint because alternative estimates for net legal immigration as of 1990 and 1996 vary as to return migration assumptions, incorporation of agricultural worker beneficiaries as United States residents, and nonspecific sources of net legal immigration. The extent of United States residence among agriculturally-legalized individuals (SAWs) has only recently been approximately estimated in research conducted for this project. The volume of transitions from unauthorized status into lawful permanent residence among family members of legalized immigrants and the timely accounting of nonimmigrants in the United States are not known with certainty. The future demographic consequences of the IRCA legalization programs could be considerable, involving as many as 3 million eventual immigrants, including at least 1 million Mexican relatives.

Legal Temporary Visitors. *Legal temporary visits between Mexico and the United States also are substantial. The border crossings between Mexico and the United States are among the busiest in the world.* In FY 1996, the Department of State issued 508,400 temporary "nonimmigrant" visas to Mexicans; 38,600 were for business or work in the United States. Additionally, an estimated 500 - 600 thousand Mexicans living in border areas have border crossing cards that permit them regular entry to the United States. In FY 1996, there were some 280 million land crossings from Mexico through the Southwest border of the U.S. (approximately 70 percent of all land crossings). At the San Ysidro port of entry alone, there were almost 40 million crossings in FY 1996, and in the first sixth months of FY 1997 there already have been almost 25 million. The top five land ports of entry into the U.S. are all on the Southern Border, including San Ysidro,

Bridge of the Americas, Caléxico, Juárez-Lincoln Bridge, and Laredo. (When the Detroit Tunnel and Bridge along the United States-Canadian border are combined, however, that will become the third largest port of entry.) Given the increase in crossings for the first half of FY 1997, this year's numbers could be the highest ever.

Unauthorized Entries. *The exact number of unauthorized entries of Mexicans into the United States is unknown. Traditionally, these entries have been measured by number of apprehensions; however, apprehensions refer to events, not individuals.* In FY 1995, more than 1.3 million apprehensions of Mexicans attempting to enter without inspection were recorded by U.S. immigration authorities. However, the same individual may be apprehended more than once, and many individuals who cross are never apprehended. Also, many apprehended individuals are local crossers, not migrants per se (Bean et al. 1994). During our site visits to Tijuana and San Diego, the research team learned that new enforcement techniques implemented in that area have caused an increase in the number of times an individual Mexican is apprehended before making a successful entry. Another new enforcement tool, the IDENT system, which stores the fingerprints of apprehended persons, may yield further data to provide an unduplicated count of the number of persons apprehended.

Trends in Naturalization. *In recent years, the naturalization of Mexican born immigrants has increased dramatically.* As noted above, recent estimates place the number of Mexican-born naturalized U.S. citizens resident in the United States at about one-half million (Passel & Clark 1997). Traditionally, only a small portion of eligible Mexican-born immigrants become United States citizens. The INS has been tracking the cohorts of legal immigrants admitted in 1977 and 1982 to determine if and when they became naturalized citizens. Overall, 46 percent of the 1977 cohort and 41.5 percent of the 1982 cohort had naturalized as of 1995. For Mexicans, the comparable proportions are 22.2 and 14.4 percent, respectively.

In the period 1961-1995, a total of 470,515 Mexican nationals naturalized, not including children deriving U.S. citizenship from their parents' naturalization. Annual naturalizations hovered between six and ten thousand during the 1960s and 1970s, but in the 1980s they more than tripled. Since then, naturalizations have continued and will continue to increase due to the confluence of several factors (from 39,310 in fiscal 1994, to 67,238 in 1995, and to 233,000 in 1996).

Interestingly, more women than men have naturalized, almost twenty-thousand more in the 1961-1995 period, and the female was greater than the male proportion in every year since 1966 except 1990-1993.

Endnote

[1] This is a lower limit because the figure does not include the emigration of complete families or of migrants who lived in Mexico alone, as there is no reporting of these people in household surveys such as the ENADID (Corona and Turián 1996c).

III. CHARACTERISTICS OF MEXICAN-BORN MIGRANTS

The demographic, educational, and income characteristics of Mexican-born migrants form a picture of their likely achievement and impact in both countries. These characteristics also mirror the forces driving migration. Unfortunately, no single data set from either side of the border provides information on all the major characteristics or on all of the varied Mexican-born subgroups. Thus, the characteristics of Mexican-born migrants have to be pieced together from a number of data sources in the United States and Mexico. These are examined here to describe how migrant groups have changed over time and how they differ from one another today.

We utilize well-known data sources and only those that reliably reflect the characteristics of the Mexican-born. All provide data on different migrant subpopulations. However, they either do not distinguish legal status or imperfectly capture the varied "types" of migrants (by time spent in the United States). For example, the U.S. Census has excellent information on characteristics, but does not capture legal status perfectly.[1] Thus, Census data do not permit contrasting the characteristics of, for example, legal permanent resident aliens and legal temporary aliens, to say nothing of unauthorized persons.

Analysis of the incomplete yet complex wealth of information available leads to three broad conclusions:

- Mexican-born migrants differ systematically along two fundamental dimensions: legal status in the United States (from unauthorized persons to naturalized citizens), and a basic migration pattern or "type" (from short-term visitors to occasional sojourners to settlers).

- Mexican-born migrants tend to have low skill levels, relative both to the U.S. population at large and to other migrant groups. These low skill levels reflect the demand for labor in sectors where Mexican-born migrants are employed and, in turn, are reflected in the low incomes and high poverty rates of Mexican-born settlers in the U.S. This situation is exacerbated by the unauthorized status of many of these migrants.

- The characteristics of migrants show increased diversity over time, consistent with the increasingly diverse demand, supply, and network factors that are shaping migration flows.

Characteristics of Migrant Types

Though data constraints are considerable, we can contrast, with representative and primarily national-level data, the following types of migrants to the United States:[2]

- *Sojourner migrant* (legal or unauthorized whose principal residence is in Mexico);
- *Settled resident* (legal or unauthorized who habitually reside in the U.S.); and
- *Naturalized U.S. citizens* (who have met five-year legal residence and other requirements).

Sojourners may be of any legal status and encompass those who come for short periods of stay for reasons varying from brief family visits and tourism, to work in unauthorized status or with legal visas—although most migrate to work. We draw on several sources to describe these mobile individuals. The primarily ones from Mexico are the 1992 national survey (ENADID), surveys at the northern border (EMIF), the Zapata Canyon project, a special survey in the state of Michoacán, and the Mexican Migration Project.

Settlers establish a usual or permanent residence in the United States, although many return regularly to Mexico and as many as one-half reestablish residence in Mexico after a ten-year stay or longer in the U.S. Eventually, many legal settlers become naturalized citizens, a process that takes time and commitment; they tend to be older and more assimilated. To describe these populations we draw primarily upon the 1990 U.S. Census, the 1996 Current Population Survey [CPS], public and special analyses of INS administrative data, and several other sources.[3]

Selected characteristics are presented in Tables III-1 and III-2 as ranges, when drawn from more than one data source, and are compared with the total or average U.S. population (native *and* foreign-born). The text below summarizes and explains the tabular results and presents additional information.

Mexico to United States migrants have tended to be selected from the middle-to-lower segments of Mexico's socioeconomic hierarchy, a selection process that originated at the start of this century with the recruitment of low-skilled workers by U.S. employers for seasonal jobs, mostly in agriculture (Bustamante et al. 1992). This flow was facilitated by the long and historically porous border that put U.S. labor markets within reach of individuals with limited financial re-

sources, by an expanding demand for low-skilled migrant workers in and out of agriculture, particularly in the southwestern United States (Alba 1992), and by extensive migration networks connecting families with low-skill U.S. jobs.

Sojourner migrants tend to be young males with little schooling who work in agriculture. Today, more than one-half of the highly mobile sojourners, particularly the seasonal workers captured in the data sources shown in Table III-2, still find employment in agriculture. Their short-term employment, however, is associated with very low earnings of as little as $185 per week, and more than one-half of their families have incomes below the poverty line.

Settled or permanent residents tend to look more like the U.S. population as a whole, even though differences between Mexican-born migrants and the total U.S. population remain substantial. Many, if not most, settlers begin their stay in the United States as circular or sojourner migrants, often as legal entrants (but also in unauthorized status) to work or live with their families. As their time in the U.S. lengthens, they gain in experience. Over time they and their families and households develop greater resources and their ability and willingness to adapt to the economy increases.

The settler population is more equally balanced between the sexes and appears to be better educated than sojourners (Donato 1993). Although, as Table III-1 shows, they generally complete only six years of education and three-fourths of those 25 years and older have not completed high school, 31 percent of those aged 18-24 are high school graduates. Moreover, 6.5 percent of all Mexican-born persons 18 and older were enrolled in college at the time of the 1990 Census. Within the settler population, legal immigrants are better educated. Among 1996 legal immigrants aged 25 and over, 35 percent are high school graduates and 15 percent are college graduates (Jasso et al. 1997). Fewer settlers than sojourners work in agriculture and, with longer-term residence and more resources, their households bring in more income. Nevertheless, as Table III-2 shows, settler household income ranges from two-thirds to about three-quarters that of the average U.S. household and twice as many live below the poverty line.

The legalization programs of IRCA formalized and speeded the transition from sojourner, to settler, to legal resident, and, finally, to naturalized citizen. There is limited information on the Mexican SAW workers who, upon legal admission, typified the seasonal agricultural or sojourner type migrant. Primarily males, most were employed in agriculture while many were likely employed in casual

urban-based jobs as well. SAWs have little education and income, but with time they are moving out of agriculture to potentially more stable households and more secure jobs—they comprised 33 percent of seasonal U.S. farm workers in 1989, but only 19 percent by 1995.

The pre-1982 legalization population typifies a settler population with a relatively balanced proportion of males and with only 7 percent employed in agriculture. Yet even in 1992, five years after legalization, they remained a population with little education; only 45 percent have completed primary education. Research finds that legalization has afforded some modest improvements, partly due to increased use of English and job training: the rate of earnings growth of legalized men 1989-1992 was greater than other U.S. workers. Two-thirds reported that legalization afforded them "easier" advancement at work. Earnings increased from U.S. $7.14 to U.S. $9.43 per hour in 1992 (constant dollars). Median family earnings were U.S. $19,112 (U.S. DOL 1996).

The number of Mexican-born becoming naturalized U.S. citizens is rapidly increasing as shown in Chapter II. Historically, the Mexican-born, along with Canadians, had among the lowest rates of naturalization of any foreign-born group. Proximity to their country of origin is a key factor. Mexican-born migrants who live in the Southwestern United States are even less likely to naturalize than their counterparts who settle in the Midwest or in New York or New Jersey, although there has been a recent surge in naturalizations among the Mexican-born. One of the more important of the many other reasons for recent trends[4] is the legacy of IRCA, those granted legal permanent resident status first became eligible to naturalize starting in 1994. Forty-three percent of legalized Mexican-born adults reported an intention to naturalize as of 1992. The surge in naturalizations, however, is not limited to the IRCA cohorts.

Longitudinal INS data on naturalization for Mexican-born persons admitted to permanent residence in 1977 and 1982 indicate that those who naturalize are drawn from among the more highly-skilled. They also experience occupational upgrading during the years between admission and naturalization. Moreover, for women, those who report work upon admission are more likely to naturalize, and labor force participation also increases between admission and naturalization. According to the 1990 Census, more than 42 percent of naturalized citizens speak English "very well" compared with 25 percent of those who do not report being naturalized. Similarly, the naturalized citizens are better schooled: 33 percent of those 25 years and older are high school graduates, compared with 24 percent of those not naturalized.

Changes in Characteristics over Time

There are some indications that the characteristics of migrants—in terms of origins and destinations, gender, age, education, and employment—are becoming more diverse over time. Migration, thus, is a dynamic process: the forces selecting people into and out of migration change over time. Migrant characteristics partly reflect the characteristics of the population-at-large from which migrants are drawn and partly are determined by selective migration forces. For example, if migrants are drawn randomly from a population that becomes increasingly educated over time, the average education of migrants will increase. The spread of migration networks may make migration "less selective" of individual characteristics over time. Increased diversity may also partly reflect changes in the kinds of worker in demand by U.S. employers. Studies document cases in which differences in characteristics between migrants and nonmigrants from specific locales in Mexico, at one time pronounced, have faded or disappeared. They also show increasing diversity of migrant origins, destinations, and demographic characteristics.

Places of Origin in Mexico. *The traditional sending states continue to dominate, but Mexican-born migrants increasingly have come from other states in Mexico.* In 1926, more than one-half of all monetary remittances from the United States were directed to the three core states of the west-central region Guanajuato, Michoacán, and Jalisco. The role of these three has diminished somewhat and today they are joined by Durango, Zacatecas, the state of México, México City, Chihuahua, Tamaulipas, and Guerrero: these ten entities represent 49 percent of Mexico's total population, but more than 70 percent of the migrant total.[5]

A broader picture of migrant sources can be constructed by dividing Mexico into six regions based on the geographic distribution of migrant birthplaces and using 1992 data:

(1) West-central core states—38 percent of all migrants: Guanajuato, Michoacán, Jalisco, and Colima;

(2) Northern-border states—21 percent of all migrants: Baja California, Sonora, Chihuahua, Coahuila, Nuevo León, and Tamaulipas (including Baja California Sur);

(3) States between regions One and Two listed above—22 percent of all migrants: Sinaloa, Durango, Nayarit, Zacatecas, San Luis Potosí, and Aguascalientes;

(4) Interior states—9 percent of all migrants: in and surrounding the Valley of México, the Federal District, the state of México, Querétaro, Hidalgo, and Tlaxcala;

(5) Four southern states—8 percent of all migrants: Oaxaca, Guerrero, Puebla, and Morelos;

(6) Six southwestern states—2 percent of all migrants: Veracruz, Tabasco, Chiapas, Campeche, Yucatán, and Quintana Roo.

In recent years, the share of migrants from rural areas appears to have fallen and a progressively larger share comes from urban areas. Traditionally migrants predominantly originated from rural areas (places with population less than 20,000). As of 1992, 59 percent of the Mexican-born who had lived in the U.S. reported coming from rural areas.[6] Nevertheless, 25 to 31 percent of migrants born in rural areas had changed their homes to urban areas.

Places of Destination in the United States. For historical, geographic, and labor-market reasons, Texas was the leading destination for Mexican-born migrants prior to the 1920s, joined much later by California and Illinois. While the southwest remained the core sending area, during the Bracero program Mexican-born migrants fanned out across a broader geographic area from Texas and California to Arizona, Indiana, Delaware, Michigan, Arkansas, Montana, and Washington. The connections to California and Texas are widespread across Mexico, but vary depending on sending traditions and networks: case studies in Michoacán indicate that communities "channel" their migrant streams to particular U.S. destinations.

Mexican-born migrants in the United States remain concentrated in a few states and localities, but increasingly they are found in new destinations. Border surveys find that the traditional predominance of Texas, California (70 percent of experienced migrants), and Illinois has continued for sojourner and settler alike. The 1990 U.S. Census indicates that the Mexican-born are highly concentrated in California, Texas, and Illinois: about 85 percent of all Mexican-born immigrants resided in these three states compared to 45 percent of all immigrants to the U.S. California is the single major destination with 50 percent of all Mexican migrants.

Los Angeles is the single most important urban destination of all Mexican-born migrants. It is followed by San Antonio, the south Texas Rio Grande Valley, Houston, Dallas-Fort Worth, El Paso, Fresno, and Phoenix.

At the same time, Mexican-born migrants have become attracted to new geographic destinations. Midwestern and eastern states with few foreign-born workers have become destinations for thousands of Mexican-born persons employed in agriculture, food processing, construction, and manufacturing operations. Mexican data show sojourners are increasingly headed to Florida, Arizona, New Mexico, and North Carolina. Although the majority of legal immigrants continue to list California, Texas, and Illinois as their selected places of residence, increasingly they go now to destinations such as Florida and Georgia.

Demographic Profile of Migrants. Mexico to U.S. migration flows traditionally were dominated by young, solo males. For example, a classic study published in 1975 analyzing apprehended migrants found that more than 90 percent were 40 years of age or younger, 92 percent were males, and 62 percent were single. The Zapata Canyon border survey, dominated by unauthorized circular migrants and sojourners, finds high concentrations of males: 97 percent in 1996.

The importance of males persists at least among sojourner migrants, although there is a trend toward more female migrants, and women dominate among new legal immigrants. The 1992 ENADID survey found that 21 percent of the Mexicans had lived or worked in the United States were women.[7] The share of males in Michoacán surveys—a traditional sending area—was 63 percent in 1983 and 56 percent 1993, indicating that more women are joining the migration stream. In contrast, the U.S. Census and other standard surveys, undoubtedly better at capturing settlers, show Mexican-born migration to be much more gender-balanced [see Table III-1]. INS admissions data on legal Mexican immigrants to the United States show that women outnumbered men for eight consecutive years between 1964 and 1971, and they outnumbered men again in 1993 and 1994.

Mexican migrants appear to be a young group, younger than migrants to the U.S. from other countries and than the U.S. population at large [see Table III-1]. This relative youthfulness may partly reflect the presence of young pioneer migrants in early migration streams and children accompanying legal immigrants.[8] The INS legal admissions data also show Mexican immigrants to be a young group with a lower mean and median age than other immigrants in the U.S.

Mexican community surveys and INS data indicate, however, that migrant ages may be increasing. The average age of Michoacán migrants rose from a mean of 29 in 1983 to 32 years in 1993.[9] Border crossing surveys for 1988 to 1996 reveal sharply rising shares of unauthorized migrants between the ages of 25-29 and decreasing shares of younger migrants. The age of women in U.S. legal admissions increased from 21 to 26 years from 1971 to 1994. Among these legal immigrants, increases in age may reflect longer waits for visa issuance and/or fewer children.

One last demographic characteristic: most migrants are married [see Table III-1]. Among sojourners, men are more likely to be married, while among settlers, women are more likely to be married. Additionally, a substantial proportion of persons who become legal U.S. immigrants do so as the spouses of U.S. citizens. Although the Mexican-born spouse flow has declined, from more than 30,000 per year in 1986-1988 to less than one-half of that in 1995, Mexico remains the leading source country for spouses of U.S. citizens. While most spouse immigrants from other countries are women, a majority of those from Mexico are men.[10]

Educational Profile. *Mexican migrants have less schooling relative to the U.S. population and other immigrant groups. Nevertheless, it appears that the average schooling of northbound migrants is increasing over time.* Sojourners average around six years of schooling. In the early 1980s, relatively well-educated villagers were likely to migrate, but their destinations were urban areas of Mexico. Over the decade, several Mexican data sources indicate increases in the schooling of U.S. migrants.[11]

Among migrants in the Michoacán surveys, average schooling increased from 4.1 to 5.8 years between 1983 and 1993. At the same time, average schooling among nonmigrants who remained in Mexico decreased from 4.5 to 4.3 years. These changes reflect shifts in migrant selectivity. During Mexico's crisis years in the mid-1980s, better-educated migrants appear to have shifted destinations to the United States.

The 1990 U.S. Census data present a similar picture of increasing educational levels: recent arrival cohorts have been better schooled. At the upper end of the educational spectrum, 4 percent of the 1980-1990 and 6 percent of the 1987-1990 migrants were college graduates. As already noted, 1996 legal immigrant complete college at a rate approaching the native-born and a higher rate of post-graduate school (9 percent compared to 7 percent) (Jasso et al. 1997) Mean-

while, the absolute number of Mexican-born doctorate holders in the U.S. 1990 Census was 3,869 (of which 27 percent were women).[12]

Labor Force Characteristics. *Work is the single most important attraction in the U.S.; however that does not mean Mexican migrants lack jobs in Mexico or combine jobs in the U.S. with usual residence there.* Most migrants had some kind of work in Mexico prior to migrating, although the share who were unemployed before migrating may be rising. Border crossing data (which include large numbers of unauthorized migrants) find that while most had work prior to leaving, the majority migrated with the intention of working in the U.S. Data also show that among females, about one-third worked outside the home in Mexico prior to migrating.

Mexican data sources reveal that those who have lived in the United States have worked there. Of course, work experience may include periodic unemployment and U.S. data show Mexican migrants have nearly double U.S. unemployment rates. As of 1992, men are more likely than women to report a habitual residence in the U.S. *and* work experience (92 percent versus 54 percent). Still, the 1992 survey found more than one million Mexican-born migrants who declared having worked in the U.S. *without* having "lived" in or established a usual residence.

Mexican-born migrants in the United States have, over time, become less likely to be agricultural workers and are found in an increasing diversity of jobs. From the turn of the century and through the end of the Bracero program, Mexican-born migrants were employed primarily in agriculture. Today [see Table III-2], most settlers and Mexican-born citizens work outside of agriculture. Concurrently, even northward bound sojourners increasingly are found outside of agriculture. Mexican data sources show evidence of an upward trend in U.S. urban-sector employment—particularly in services and construction—for unauthorized migrants [see Appendix B]. Still, Table III-2 shows that Mexican-born workers retain an industrial profile that differs from the U.S. average.

Income Characteristics. Mexican-born households are much more likely than all U.S. households to be found at the bottom of the income distribution. The 1990 Census shows that the share of households in the lowest income groups was greater for the recently arrived 1980-1990 cohort and lower for the pre-1980 cohort. The share in the highest income groups was higher for the earlier cohort. This suggests the possible operation of two mechanisms: expe-

rience in the U.S. leads to higher earnings and/or the less successful migrants in the earlier cohorts returned to Mexico, leaving the higher earners.

A 1996 U.S. survey finds that, while the average U.S. household saw income gains between 1990 and 1996, Mexican-born households lost income. On average, all U.S. households brought in $38,453 in 1990 and $44,938 by 1996. In contrast, the average U.S. Mexican-born household brought in $27,122 in 1990, but only $26,481 in 1996. Comparison of median household income shows the same relative loss in the incomes of Mexican-born households (all figures in current dollars). The 1996 data reveal a concentration of new (1990-1996) migrant households at the bottom of the income spectrum: 11 percent of recently arrived migrant households have incomes less than $5,000, double the proportion of earlier arrivals. This may reflect differences in the legal status mix, for example, a larger proportion of undocumented among the recent arrivals. It also may reflect the lower earnings at entry among some of the IRCA-legalized aliens. Recent legal immigrants in 1996, for example, have higher earnings. A recent survey indicates earnings of $19,130 for adult male and $13,620 for adult women immigrants (Jasso et al. 1997).

Endnotes

[1] Information on the characteristics of citizens is biased because of substantial misreporting of naturalization by noncitizen settlers (special tabulations by Jeffrey Passel, Urban Institute). However, the systematic differences between settlers and citizens appear to be reasonable approximations.

[2] To obtain a picture of the sojourner, we piece together data from numerous sources: the National Survey of Demographic Indicators [Encuesta Nacional de Indicadores Demográficos, or ENADID], the Survey of Migration at the Northern Border [Encuesta sobre Migración en la Frontera Norte, or EMIF], the Mexican Migrant Survey undertaken jointly by COLEF and a team of researchers from the University of Southern California [USC], the Mexican Migration Project, the Michoacán Project, INS Data on Nonimmigrants (Temporary Visitors), the UC-EDD Survey of California Farmworkers carried out by the University of California, Davis [UC], the State of California Employment Development Department [EDD], and the National Agricultural Workers Survey [NAWS] conducted by the U.S. Labor Department.

[3] For pictures of the settlers and U.S. citizens, we rely on two main U.S.-side data sources: (1) the decennial censuses, including microdata as well as historical time series published in Historical Statistics of the United States; (2) official government information, including microdata compiled by the U.S. Immigration and Naturalization Service [INS], tabulations published by the INS in its Annual Report (published 1943 to 1977) and the successor Statistical Yearbook (published since 1978), tabulations published by the U.S. Department of State in its annual Report of the Visa Office, and a special microdata sample assembled from INS data by the General Accounting Office [GAO]. Of these, only INS data provide information on legal status; and measurement of naturalization in the censuses is problematic.

[4] These factors include: visa backlogs for spouses and minor children of permanent resident aliens, largely due to IRCA legalizations; the Green Card Replacement Program, initiated in 1992, which requires that permanent resident alien cards issued before 1978 be replaced and which leads some to naturalize rather than obtain a new green card; initiation of an expiration date, ten years after issuance, on green cards issued since 1988, which may similarly lead some to choose naturalization over green-card renewal; recent U.S. legislation which dramatically reduces the civil rights and social entitlements of nonnaturalized immigrants; and recent amendment of the Mexican Constitution that provides that Mexican nationals who become naturalized citizens of another country do not automatically forfeit Mexican nationality.

[5] The share of migrants in a state's total population varies. It is highest in Zacatecas, where 9.7 percent of the population had lived or worked in the United States. It is 8.3 percent in Durango, 8.2 percent in Michoacán and 6.5 percent in Jalisco. In contrast, the share is only 0.9 percent in México City, and 1 percent in the state of México.

[6] As of 1992, there were marked differences in rural versus urban origins across regions. While the Valley of México and border regions have small shares of rural migrants, 32 percent and 34 percent respectively, in other regions the rural share is more than 60 percent.

[7] The share for those who had lived in the U.S. over the previous five years was 24 percent, suggesting that the female share is increasing slightly.

[8] For example, in the nineteen communities studied by Massey and Durand, the average age of migrants in the United States at their most recent trip was 29 years. The average age of unauthorized migrants in the Michoacán surveys, who comprised just over 58 percent of all 1993 migrants, was younger at 28.5 years than legal migrants at 37 years of age.

[9] The 1983 migrants were somewhat younger than nonmigrants, whose average age was 32, but the 1993 migrants were considerably older than nonmigrants, whose average age was 20.

[10] INS public-use data do not include sponsor's nativity, but a special study carried out by the General Accounting Office [GAO] on data from 1985 indicates that almost 78 percent of the U.S. sponsors of Mexican-born spouses were U.S. citizens by birth (worldwide, the rate was 80 percent). In an intergenerational twist on the international character of these couples, among the birth-citizen sponsors in the GAO sample, 4-5 percent were themselves born abroad to U.S. citizen parent(s).

[11] The Mexican Migrant Project show increased schooling and increased schooling is one of the more salient findings of the Zapata Canyon border survey. Mexican data for 1978-1979 found migrants had 4.9 years of schooling on average, slightly greater than the 4.7 years for the Mexican population over 14 years old.

[12] Note that Census data do not reveal whether these are persons undergoing further training or engaged in postdoctoral work with nonimmigrant visas as opposed to permanent residents of the United States.

IV. CAUSES OF THE MIGRATION NORTHWARD

For most of the twentieth century, the major linkage between the two most populous countries in North America has been the migration of people from Mexico to the United States. "Go north for opportunity," is an idea deeply embedded in Mexican youth, especially in the rural areas of west central Mexico.

Many factors cause and sustain this movement of Mexicans across the border to work temporarily or to settle in the United States (Massey et al. 1993). We group the factors that sustain Mexico-United States migration into three broad categories: (1) demand-pull factors in the United States; (2) supply-push factors in Mexico; and (3) the networks of human contacts that bridge the border.

Our analysis leads to a simple conclusion: the migration of persons from Mexico to the United States is a dynamic process. What began largely as the U.S.-approved or U.S.-tolerated recruitment of Mexican workers for seasonal U.S. farm jobs has become a far more complex migration flow that is sustained by supply and network factors. Our key findings are that:

- The catalyst for much of today's unauthorized Mexican migration for United States employment lies in the United States, but over time new factors have created a larger and more complex set of reasons that sustain the flow;

- The same tendencies that currently seem to be increasing and diversifying Mexico-United States migration flows may be dampened or reversed starting in the next fifteen years. These demographic and economic trends, if sustained, could reduce pressure for Mexico-United States migration.

Starting & Sustaining Factors

Mexico-to-United States migration is primarily economically motivated and the initial motivations for the migrant flow lie largely inside the United States—Mexican workers were recruited by U.S. farmers earlier in the twentieth century, creating linkages between jobs in U.S. agriculture and workers in particular Mexican communities. We find that there is still a demand-pull for Mexican workers in the low-unemployment U.S. labor market in the sense that most recently-arrived legal and unauthorized Mexican migrants can find jobs in high turnover farm, manufacturing, and service jobs. Low-skill Mexican workers are employed both in areas where Mexican-born workers traditionally have played important roles, as in southwestern agriculture, and now in industries in the Midwest, the southeast, and east coast, including construction, meatpacking,

and services. In some cases, including poultry and meat packing, private labor brokers and recruiters continue to play an active role in moving Mexican workers to jobs in the Midwest and southeast.

However, the factors that initiated Mexico-United States migration are not necessarily the only ones that sustain the flow. Today cross-border networks of relatives, friends, and labor brokers and recruiters link an expanding list of U.S. industries, occupations, and areas to a lengthening list of Mexican communities that send migrants to the U.S. In Mexico, residents of some communities have better information about the availability of certain types of U.S. jobs than do nearby U.S. residents.

Supply-push factors in Mexico play as fundamental a role as the availability of U.S. jobs in sustaining Mexico-United States migration. Supply-push factors seem to have become more important since the mid-1980s as a result of rapid population growth in the 1970s, recurring Mexican economic crises, peso devaluations, and Mexican policies aimed at economic modernization, such as the privatization of government-owned industries that resulted in layoffs and the restructuring of rural Mexico that made small-scale farming less profitable (Roberts & Escobar Latapí 1997).

This means that Mexicans migrate to the U.S. (1) within well-established networks, as well as (2) through new networks that are developing to move migrants to the U.S. from regions without a tradition of Mexico-United States migration, such as Mexico's urban areas and the southern states identified in Chapter III. Friends and relatives established in the U.S. often provide financing, advice, shelter, and jobs to newly-arrived unauthorized migrants. Settled family members in the U.S. use family unification policies to have spouses and children join them and eventually to secure legal migrant status.

In some areas of west central Mexico, the data suggest that migration to the U.S. has become a way of life. Based on migration histories collected in thirty-nine communities that have long histories of sending migrants to the U.S., we estimate that by the time they are 40, most of the men in some of these communities have made at least one trip to the U.S. Based on a statistical model that predicts migration to the U.S. on the basis of age and community characteristics, it appears that in some communities the probability that a young man will make a first trip to the U.S. increased after 1992.

Evolving United States Labor Markets & Legislation

The United States labor markets where Mexican migrants work are changing and may change even more as a result of technological advances, trade trends, and labor force and legislative changes. On the demand side of U.S. labor markets, employers are adjusting to higher minimum wages and more global competition. On the supply side, the U.S. retains a sizable low-skilled labor force. Recent welfare reforms may add to the supply of low-skilled U.S. workers seeking employment, most notably in sectors where Mexican-born workers are concentrated (nine of ten Mexican-born workers in the U.S. hold nonfarm jobs, often in low-skill industries). High immigration since the 1980s, legalization in 1987-1988, and changing hiring practices have made Mexican-born workers significant components of the U.S. food processing, construction, service, and manufacturing labor forces.

Employment Trends. *It is not clear whether the U.S. labor market will continue to evolve in ways that absorb large numbers of Mexican migrant workers.* On the one hand, the U.S. unemployment rate dropped to its lowest levels in twenty-five years in 1997, and there are reports of labor shortages, especially in low-wage labor markets in areas with unemployment rates of less than 2 percent, such as the Midwest. Job growth has been very rapid: between January 1994 and June 1997, the U.S. economy added about 8 million jobs. With Mexican-born workers spreading throughout the U.S. in a period of rapid job growth and low unemployment, networks that bridge the border may be strengthened, increasing the demand for migrant workers and making Mexican migrant workers a permanent feature of more U.S. industries and areas.

On the other hand, the U.S. is committed to implementing more border and interior controls, to moving 2 to 3 million adult welfare recipients into jobs, and to creating jobs for the rapidly growing domestic labor force. The U.S. labor force, which usually expands by about 1 percent per year, has been expanding about twice as fast due to international migration, welfare recipients moving off the rolls, more older men working, and an increase in the percentage of working-age women seeking jobs. In January 1997, a record 67.2 percent of the U.S. population 16 and older was in the labor force, employed, or looking for work, for a total of 136 million persons.

It is hard to project the evolution of labor markets that migrants traditionally enter. In many areas of the U.S., migrant workers, a fear of labor shortages, and high welfare caseloads go together. For example, in the San Joaquin Valley of

California, about 85 percent of the 400,000 individuals who work as farm workers sometime during a typical year are foreign-born, including 100,000 or more unauthorized migrants. Farmers fearful of labor shortages are calling for modifications of the H-2A program that would make it easier to obtain temporary foreign farm workers (reducing wage and housing protections for both the H-2A and other workers). At the same time, local conditions suggest that workers are available: 25 percent of the 761,000 residents of Fresno county are receiving some form of welfare assistance, and many may soon be seeking employment in a competitive labor market with an unemployment rate of over 14 percent as of April 1997.

Border Enforcement Strategies. *The United States border enforcement strategies begun in 1994 are affecting migration patterns, but not preventing unauthorized entry*. The major programs begun since 1994, 1995, and 1996 are "Hold-the-Line" in El Paso, "Gatekeeper" in San Diego, and "Safeguard" in Arizona, respectively. Our research along the border found that migrant smuggling has achieved enough regularity and volume to become an established business with three segments: local agents; local and border smugglers; and border-only smuggling businesses—each with a menu of prices and services. As border control operations were stepped up in 1994, more migrants turned to smugglers or "coyotes," whose services became increasingly diversified. Thus, unauthorized migrants have several available packages of services and several options to pay for the cost of illegally entering the U.S., including working in a coyote-provided or coyote-arranged job in the U.S.

Our survey in Jalisco in January 1996 found that most Mexicans attempting unauthorized entry into the U.S. hire smugglers to help them cross the border. Migrants with the fewest network links to bridge the border are most likely to rely on the smugglers who operate as border-only businesses; one-half of the migrants who have no networks in the U.S. turn to these border-only coyotes. The increased use of coyotes generally, and particularly at the border, helps to explain why most migrants attempting unauthorized entry succeed despite significantly more U.S. Border Patrol agents and technology on the border. It remains to be seen whether or not triple fences, augmented border strategies, and more effective internal employer sanctions enforcement will have deterrent effects over the long run.

Outlook. These trends suggest several scenarios. One is that migrant labor markets will segment with different employers /industries pursuing different

strategies. Some U.S. employers, reacting to low unemployment and welfare reforms that limit assistance for migrants, may offer English and other services to help their migrant employees become naturalized U.S. citizens. Other U.S. employers, such as farm labor contractors, may go further into the underground economy to avoid labor law and immigration enforcement, hiring recently arrived migrants despite high unemployment rates that prevail in their regions. Further segmentation of migrant labor markets could mean that networks may become more important, with the ability to get into the upper segment of the unskilled migrant labor market being the key to economic mobility in the U.S.

Migration & the Future

We find that there is reason to believe that currently high levels of Mexico- United States migration may represent a "hump" or peak in the volume of Mexico- United States migration. Within the next fifteen years, we think that demographic and economic factors within Mexico are likely to reduce emigration pressures.

Structural Changes and People Seeking Work. *A major long-term supply-push factor explaining the mid-1990s migration hump and the eventual decline in emigration pressure is demography—the number of new job seekers entering the labor force in Mexico has been very high, but will decline.* Between 1993 and 1997, Mexican National Employment Surveys indicate that employment increased from 32.4 million to 36.7 million, by about 3 percent per year, adding about 1.1 million paid and unpaid jobs per year.[1]

A declining birthrate since 1970, when Mexican women averaged nearly seven children each reduces the need to create additional jobs,but Mexican women today average less than three children each, a downward trend that appears to be continuing. Net growth of the labor force ages 15 to 44 is projected to drop to 500,000 to 550,000 per year by 2010.

Our longer-term perspective emphasizes that these demographic trends, in combination with other patterns in Mexico and the United States, may reudce Mexico-to-United States migration.[2] Within Mexico, the effect of demographic factors on reducing emigration pressure could be magnified if, for example, more young persons follow the trend of staying longer in Mexican schools. Migration networks are most established in rural areas with long traditions of sending young men to the U.S., including the areas of Mexico currently undergoing structural change. But Mexico's rural restructuring can displace workers from agriculture only once. After the Mexican farm labor force has been reduced from 25 per-

cent of all workers in the mid-1990s to 12 to 15 percent by 2015, supply-push emigration pressures from the areas that have some of the best network connections to the U.S. should diminish.

As the number of persons employed in Mexican agriculture shrinks, and some ex-farmers are absorbed into Mexico's service economy, there should be fewer Mexicans with strong network connections ready to migrate to the US. The destabilizing impacts of Mexican institutional and market reforms should run their course. If current and projected moderate economic growth is sustained—both in the rural sector and in the new export-oriented activities in Mexican urban areas—then jobs and upward pressure on wages should encourage many potential migrants to remain in Mexico.

Projections of Job Growth. *Mexico adopted an ambitious restructuring and privatization program in the 1990s that promises to increase economic efficiency and job growth in the medium- to long-term* (although it will displace workers in the short-term). If Mexico maintains market-driven economic policies, the International Monetary Fund projects 5 percent annual economic growth and 2.5 percent employment growth for 1997 and thereafter—given this two to one ratio between real GDP growth and employment growth, there would be 750,000 new jobs created each year, based on 30 million employers, self-employed workers, and wage and salary employees. Even if economic growth is less than the IMF forecast, the Mexican economy may be able to generate enough jobs for the smaller entry labor force cohorts projected for the years after 2000.[3] If Mexico is able to generate this additional employment, emigration pressures should diminish. Substantially lower growth rates, however, would slow down this process.

Another promising sign is the recent growth of jobs in the formal economy. The number of permanent workers enrolled in the Mexican Institute for Social Security [IMSS] rose by a record 661,024 in 1996 to 9,163,459, an expansion characterized by the OECD as "strong job creation in the 'formal' economy" (OECD 1997:98). However, interest rates remain high, and the recovery is unequal, accentuating inequality (Escobar Latapí 1996).[4] Mexicans linked to the world economy via exports of manufactured goods are doing much better than those operating only in the domestic economy, such as personal services, traditional manufacturing, construction, and small-scale agriculture. The latter still represents the largest sector for employment.

Differences in the speed of recovery among economic sectors is accompanied by differences among Mexican regions. For supply-side pressures to lessen, economic and employment growth should reach those sectors and regions with strong migration networks.

These medium- to long-term economic and demographic considerations suggest that supply-push emigration pressure should decline from current levels. We emphasize this point because it is easy to focus on recent events that point to increases in emigration pressure, including the peso devaluation and economic crisis of 1995, and the uneven recovery from recession. And, of course, economic factors are less certain: Mexico has experienced uneven economic growth over the past several decades and could experience recessions and crises again.

Sustained economic growth and the current growth-jobs ratio, plus a projected decline in the number of new job seekers, means that early in the twenty-first century Mexico could be creating enough net new jobs to absorb new labor force entrants. Mexico could then begin to catch up on job creation for currently unemployed and underemployed workers, those displaced from agriculture and other industries, and nonworking women who rejoin the labor force.

Thinking about Mexico-United States Migration

We find it useful to think of migration processes between Mexico and the U.S. as being analogous to a river that creates a delta on its way to the ocean. When the Bracero program was in operation, the flow of Mexicans north was largely confined to the channel created by legal recruitment. Blocking that channel by abolishing the Bracero program in 1964 enabled the U.S. to stop the migration flow temporarily. The migration soon resumed, however, with a myriad of small streams becoming the channel for Mexicans migrating north. Visualizing Mexico- United States migration as having evolved from a narrow channel to rivulets meandering through a delta provides insights into a complex and dynamic migration process.

Both the U.S. and Mexico took steps over the past decade that reinforced the network and supply-push factors that encourage Mexicans to go north for opportunity. As we saw in Chapter II, the U.S. legalized more than 2 million Mexicans in 1987-1988, including almost 1 million farm workers. The long-term (pre-1982 arrival) legalized population is poised to sponsor a large number of legal admissions. The legalized agricultural SAW workers were the equivalent of one-sixth of the adult men with paid jobs in rural Mexico; they also gained the right to settle in

the U.S. and petition to bring their families to the U.S. legally. Ironically, one U.S. government commission concluded that the SAW farm worker legalization program promoted unauthorized Mexico-United States migration by giving the impression that doing unauthorized farm work in the U.S. was a way to become a legal immigrant (Commission on Agricultural Workers 1992).

In the early 1990s, Mexico undertook measures that may compress into a decade or less what would otherwise have been a slower shrinking of employment in agriculture. Mexico eliminated most input subsidies and price guarantees in agriculture, switched to direct payments to farmers, and eased trade restrictions, signaling the eventual shrinking of the production of many commodities, notably corn, that today absorb a great deal of labor, but in which Mexico does not have a comparative advantage.

Extensive networks of family, community, and private agents have developed to assist Mexicans wishing to migrate legally and illegally to the U.S., including a variety of advisors, smugglers, and transportation agents. The migration infrastructure has become very sophisticated. Migrants have choices in deciding who will help them to cross the border, in choosing how to finance the trip, and in finding U.S. employment.

If the underlying demand-pull, supply-push, and network factors change in strength and relative importance, policies designed to deal with just one factor at one level of migration may lose their effectiveness over time. For example, U.S. policies that were based on the assumption that the major factor sustaining Mexico- United States migration was legally-authorized demand-pull U.S. employer recruitment became less effective in the 1970s and 1980s as the key factors sustaining migration shifted to informal U.S. employer recruitment and supply-push and network forces. In such circumstances, simply stopping legally-authorized foreign worker recruitment did not stop migration. There is a need for policymaking that avoids the "law of unintended consequences," that uses a combination of approaches, is effectively implemented, and to the extent possible has the support of both governments.

Endnotes

[1] The 37 million persons currently in the labor force include about 4 million unpaid family workers and 2 million unemployed workers (those classified as employers or wage and salary workers totaled about 30 million in 1997).

[2] The U.S. labor market is expected to absorb a large number of unskilled workers over the next few years, as the normal complement of new job seekers are joined by persons removed from welfare rolls. This increased supply of U.S. workers, as well as even more border and interior enforcement, may reduce the availability of jobs for newly-arrived Mexican workers.

[3] Mexico's total labor force may grow, as persons not in the labor force seek work if jobs are available. A "tight" labor market will not ensue immediately because there is a reserve of inactive, unemployed, and underemployed persons that these shifts in supply and demand should gradually accommodate.

[4] Inequality has increased. According to the 1997 UNDP Human Development Report, the richest Mexican *person* has assets equivalent to the *combined incomes* of the poorest 17 million Mexicans.

V. ECONOMIC & SOCIAL EFFECTS IN BOTH COUNTRIES

Migration has repercussions through labor market supply and demand, through fiscal implications for national and local governments, and on political and social institutions. Some of the differences in perspectives on migration's impacts—favorable or adverse—come from very real differences observed in the populations in each country. In Mexico, those who return most often are the sojourners who may bring some benefits of their U.S. experience back with them. In the United States, it is the settler population, often older and sometimes unauthorized, whose relatively low skills place them at a disadvantage in an "information age" economy. Thus, disparate pictures emerge depending upon which end of the telescope one looks through.

Mexico & Migration Effects

Migration has many impacts on Mexican national development, the most studied of which are the economic consequences flowing from migrant remittances and from the interaction of labor supply and demand in Mexico and the United States. Numerous caveats must accompany any conclusions about the impacts of migration in Mexico, including variations in impacts across regions and through time and national-level versus regional or community- specific effects. Migrants originate from villages, towns, and cities throughout Mexico, but intense migration is most heavily concentrated in just 109 of Mexico's more than 2,400 municipalities (similar to U.S. counties) and in 9 western and northern states. And today's migration, while increasingly of an urban character, remains strongly influenced by rural conditions.

Distinctions also need to be drawn between communities with a "long tradition" of migration and those more recently incorporated into migratory flows, for migration experience shapes impacts. The nature of a community's migrant flows—temporary, recurrent or permanent—will create variations in impacts. Most of the information available to estimate effects of migration comes from community studies, many of which do not cover the full range of possible impacts. Special attention has been given to remittances and their effects on the well-being of migrants, their families and their communities. Most detailed studies to date have focused on rural areas in a few states, and more research clearly remains to be done.

Economic Effects

Remittances to Mexico and National Multiplier Effects. Migrant remittances represent the most direct and measurable benefits of international migration on Mexico (Lozano 1993). The benefits received by the communities from remittances depend on: (1) the number of households with migrants employed abroad; (2) the relative importance of remittances as compared with other sources of income (estimates of remittances as a proportion of income from all sources range from 5 to 93 percent); and (3) on whether or not the community is capable of retaining the multiplying effects of remittances. It is common for the benefits derived from consumption and investment to be concentrated in the important regional cities. The diversion of remittances to these regional centers is a topic that merits special attention.

Remittances of permanent migrants represent about two-thirds of the total, and as these migrants tend to reduce their remittances as time passes, it is anticipated that their contributions will diminish in the future.

Temporary migrants, on the other hand, incur higher costs of mobility (especially if they are unauthorized), lesser residential costs, and lesser costs for the United States due to their limited demands on health, education, and other services.

At the national level, remittances reached a considerable overall figure of between U.S. $2.5 and U.S. $3.9 billion in 1995. Remittances are equivalent to more than one-half (57 percent) of the foreign exchange available through foreign direct investment in the same year. This represents a little less than 5 percent of the foreign exchange obtained by Mexico for the export of goods.

Remittances over time are mostly concentrated in the same few states and areas of origin. There the remittances have greater economic importance. For example, in the state of Zacatecas, migrant income was higher than federal revenues in 1988.

The amount remitted per migrant was around U.S. $700 in 1995, but this figure is very different for permanent and temporary migrants. Alternatively, the net amount of remittances per receiving household is equivalent to one average wage in places of origin. In a context in which 60 percent of households' earnings are below that average, the amount remitted is of great importance.

To gauge the full effect of remittances, one needs to measure more than just the quantity of remittances and how they are spent. Economic simulations of

remittances attempt to estimate these complex effects (Taylor 1996). Estimates represent not only the direct effect of migrant remittances on the households that receive them, but also the indirect effects across all households that result from their spending. Remittances produce the largest income multiplier when they flow into Mexico's rural households, whose consumption and expenditure patterns favor goods produced domestically with relatively labor-intensive production technologies and few imported inputs. When migrant remittances go to urban households, more of the money leaks out of the country in the form of import demand. Based on these multiplier estimations, which are partial pictures of a complex reality, it estimated that for every dollar sent or brought into Mexico the gross national product [GNP] increases by about U.S. $2.90. Each dollar in remittances may translate into an increase of U.S. $0.3 to U.S. $0.4 in the income of small farmers and rural workers; and U.S. $1.10 in the income of urban-worker households (although urban households do not receive most remittance dollars, they benefit from rural household's demand for urban goods and services) (Adelman & Taylor 1990).

As the North American economy becomes increasingly integrated, remittance multipliers in Mexico are likely to decrease as production in Mexico responds more to demand in the North American market as a whole and less to demand in Mexico alone. In a North American free trade area, migration may affect production and incomes in Mexico in new ways.

There is a wide variety of migration experiences among the migrants; these differences are reflected in remittances. Frequently, especially now, remittances are limited to covering families' expenditures with nothing going to savings. In such cases, remittances may still have a relatively high impact on those families as this income becomes a sort of survival insurance.

Remittances are also dependent upon circumstances that might reduce their importance. At the extreme, up to one-third of return migrants do not manage to send remittances or take money home with them upon return. In other cases, the earnings that finally reach families are not high, partly because there are considerable losses in the remittances, but above all because migrants have heavy expenses both on the journeys to the U.S. and back and during their working stay in the U.S. These expenses are generally greater for unauthorized migrants than for residents or for temporary migrants with documents. There is some evidence that migrant wages recently have dropped and of labor competition among Mexican migrants themselves. Also, particularly in agriculture,

it is common to face periods without work and, therefore, without income. For these reasons, remittances for such families are cyclical, unstable, and unequal.

In contrast, some studies suggest that there are workers in more stable work and some who manage to obtain employment more quickly, perhaps because of their previous experience or their contracts through established networks. In such cases, their savings, after deducting expenses, can be anticipated and more efficiently channeled to their families.

Remittances, Investment, and Development. Remittances have two types of impact on communities. In most cases remittances become a source of support for family consumption, housing improvement, and basic urban services. Yet, other communities show productive changes in which the remittances play an important role as a source of investment. On occasion that role is complementary to the development process driven by other local and regional forces.

The impacts can be shown by using social accounting matrices. These have been constructed for a handful of specific communities, estimating different multiplying effects of remittances. These effects vary depending on the degree of development previously reached by the localities, as well as on their economic links with other communities and on the importance of remittances in relation to other income in the community. It is clear that when a sending village does not have an adequate source of income, remittances are of paramount importance.

Other studies we have carried out suggest similar trends with respect to the relationship between "migratory intensity," migratory "trajectory" in time, and the economic performance of communities. In localities where the wage of the formal sector is greater, lower rates of migratory activity are observed. Similarly, higher wages are related to a reduction in migratory intensity over time. Of course, the causality may run in either direction, but it is important to suggest that economic improvement eventually will reduce migration.

According to the literature, most migrants' families invest their remittances primarily in improving their housing and, to a lesser extent, in productive investments. For the nine major sending states, we found that migratory intensity is associated with improved provision of services for housing and a greater use of modern agricultural technology. These are probably the most important effects stemming from remittances we found.

Remittances also enable many communities to overcome capital constraints and to finance public works projects, such as parks, churches, schools, electrification, road construction, and sewers. The impacts and changes reported at the community level are generally in keeping with findings reported in other parts of the world. Our interpretation coincides with others who view remittances as a vehicle for furthering the development of migrant areas. The benefits increase as long as the channeling of remittances goes hand-in-hand with other conditions, such as the concentration of private and public resources in the same areas, notably on infrastructure.

Possible Productivity Gains from United States Work Experience. There is some evidence that working experience in the United States may produce additional benefits to migrants when they return to Mexico. Such a bonus would be realized as improved earnings (Greenwood & Tienda 1997), if they are able to capitalize on their experience acquired.

Demographic Impacts

It is estimated that 7.0 to 7.3 million Mexicans were residents in the United States in 1996.[1] Although a small figure in comparison with the total Mexican population, this represents more than 7.9 percent of the population from Mexican sending states. Most of this loss involves persons in their working ages.

Projections for the major sending states suggest slowing population growth in the next century. Assuming current rates of migration, growth rates would fall from 2.1 percent today to 0.6 percent in 2010. Assuming no migration, growth rates would fall from what would otherwise be 3.1 percent today to 1.4 percent in 2010. In these states, the loss of population due to past and ongoing outmigration is projected to reduce the potential growth of the working age population by 46 percent.

Social Effects

Costs of Migration for Mexico. The loss of human capital is the most important cost to Mexico. These costs have commonly been estimated to be small by assuming an excess of redundant labor in the developing sending country. However, for Mexico this assumption is questionable because of the selectivity or characteristics of its migrants. Family and community costs have only recently received attention.

The loss of human capital could be estimated by looking at the costs of education, health, and social infrastructure incurred throughout the life of individuals to achieve an economically active person in good working conditions. The cost for Mexico in human capital is the "opportunity cost" represented by having invested in preparing that person and having foregone the value added of the migrant's productive economic activity. The net returns on Mexico's investments in that person are those remittances or savings sent or brought to the country.

There are relative costs or returns. By return we understand the quotient between what is obtained as a wage or added value and what is invested or spent in exchange for that product. For Mexico as a country, the return is small if we consider the quotient between the amount saved from the wage paid to migrants and the costs of education, health, etc., incurred. The return on migrants is only in relation to the net amount in remittances or savings, as approximately 90 percent of what they receive in the United States is consumed there. In this regard, it is incorrect to associate the total U.S. wage with Mexican earnings.

Family and Community Costs. Migration is accompanied by significant changes in family organization, such as a necessary additional work effort by families to compensate for the migration of one or several of their members. Similarly, in the communities with the greatest migration, major changes occur in those communities' social and political organizations, which frequently make themselves felt in adverse ways. It is common for the young people with the most initiative to leave, with the result that communities lose their current and potential leaders as well have a weakened capacity for interaction with the exterior. The actual or potential loss of labor to migration may push up wages and create uncertainties that discourage investment and training of workers in places of high out-migration. It is also common for migration to be accompanied by serious problems of family disintegration, as well as by different psychological and social problems that previously were nonexistant in the communities of origin. Although such social costs are difficult to estimate accurately, observers realize their great importance in the communities of out-migration. Systematic research would be invaluable.

The United States & Migration Effects

The impacts of Mexican migration in the United States today may differ from those of the past because of changed economic and sociopolitical circumstances. There is extensive evidence that since the mid-1970s the earnings and employment of more educated workers have been improving relative to the less-skilled. This may translate into more limited economic mobility for today's migrants which, coupled with reductions in welfare and health benefits, increases the challenges of integration and adaptation.

These conditions fuel perceptions that the costs of migration exceed the benefits. Much evidence refutes this view—with the qualification that not all segments of society share equally in the benefits or bear equally the costs. To capture this distributional nature of impacts, we distinguish national, regional, and local impacts. We also separate economic, demographic, sociocultural, and political consequences, although these dimensions are interrelated.

Our major observation is that the failure to recognize distributional issues is an important source of misunderstanding about the benefits and costs of migration in general and of Mexican migration in particular.

- Therefore, we take as our point of departure the simple premise that Mexican migration produces economic benefits for the United States, but that these benefits come at a cost for some. Our main task then is to identify the particular benefits and costs of Mexican migration, and to specify which groups gain and which lose.

Such a balanced and nuanced portrait of impacts is crucially important for contemplating policy strategies. Simply stated, most impacts of Mexican migration will be more pronounced in locales and industries where migrants reside and work. However, short- and long-term impacts differ, some impacts are transmitted intergenerationally, and many benefits and costs cannot be quantified.

Economic Effects

Most researchers report that industry case studies uncover evidence of competitive effects of migrants. Most national-level analyses, however, typically find that the wage and employment effects of increased migration on native-born groups are not great; rather, the largest impacts are on other foreign-born workers (like the migrants themselves).[2] To evaluate these generalities, we reviewed all of the most recent empirical literature and performed a new econometric analysis.

Industry Case Studies. Employment displacement effects of migrant workers are evident in certain industries in regions, such as Los Angeles and New York, where migrants are concentrated. These may occur because the ready supply of migrant workers places downward pressure on industry wage rates. Alternatively, the displacement may occur because employers "prefer" or find it advantageous to hire new migrants even when natives are available at comparable wages. A shortcoming of most case studies is that they do not trace the ultimate outcomes for native workers who presumably find new jobs, but sometimes at a considerable cost.

The favorable aspects of these effects accrue most clearly to the migrant worker and to foreign and native-business owners. It is often observed that immigrants are highly entrepreneurial and that foreign-owned businesses contribute to the U.S.'s legendary job-creating, small business sector. *Some Mexican migrant worker networks have positive effects for small and large foreign- and native-owned businesses.* In many such businesses, migrant workers and employers appear to strike a bargain that benefits both: in exchange for lower starting wages, the migrant gains informal job training from the employer. The efficiency and speed with which networks operate gives employers ready access to a pool of workers vouched for by the employers' current workers. These hiring networks reduce search costs, reduce the likelihood of "problem workers," and provide redundancy during times of peak production or when employees are out sick.[3]

Impacts on Business and Workers Nationally and Regionally. Because they are so specific, it is difficult to generalize from case studies. Therefore, we undertook a statistical analysis of 122 metropolitan areas using the 1990 census. We introduced several analyses that permit us to unbundle effects to regions and metropolitan areas. The results of these econometric excercises are discussed below.

The primary beneficiaries of migration are, of course, the Mexican-born migrant workers. As discussed earlier in this chapter, migrants and their families consider the opportunity cost of migration; they balance the costs and benefits of working in the United States against their opportunities if they remain in Mexico. With a wage differential of at least five to one, the Mexican-born migrant working in the United States benefits from a higher standard of living.

Owners of capital, that is business owners and investors, are clear winners. We measure the effect of Mexican-born migrants on the "real rental price of capi-

tal." For example, a positive migrant effect means that an owner of a machine shop is able to charge a higher amount for a tractor or water pump rental. In California's metropolitan areas a 20 percent increase in Mexican-born migrants increases the return to capital by 0.8 percent on average. Agricultural areas benefit more, Merced and Salinas by 1.7 percent each and Visalia-Tulare by 1.4 percent. For Texas, a 20 percent increase in migrants is associated with a 0.3 percent increased return to capital on average. But the returns to border areas are greater: Brownsville 1.4 percent, El Paso 1.6 percent, and McAllen-Endinburg-Mission a 1.8 percent increase.

Shifting to the effects of Mexican-born migrants on the wages of other labor force groups, we find that *the principal adverse impact is on already-resident migrants from Mexico or elsewhere.* In our model, a simulated 20 percent increase in the number of foreign-born, low-skill Mexican workers lowered the average wage of this labor group by 3 percent, but left the wages of other labor categories almost unchanged. Next we simulated the direct wage impacts of Mexican-born labor, on average, for several metropolitan areas within a given region.

For the average United States region, even relatively large increases in Mexican-born labor have only relatively small impacts on native workers. Metropolitan areas in California and Texas have relatively heavy concentrations both of Mexican-born persons and of native-born persons of Mexican ancestry. The major impact of a 20 percent increase in foreign-born, low-skill Mexican labor in California is on other foreign-born, low-skilled Mexicans. Their wages fall by 6.9 percent and their employment declines by 1.3 percent. Otherwise, there are only minimal impacts on other skill or immigrant groups. The results for Texas, Arizona, New Mexico, and Colorado are similar to those for California, but for the most part are more moderate.

Empirical evidence appears to indicate that in areas where Mexican migrant concentrations are extremely high, such as along the southwestern border, wage depression and job displacement effects are evident. These impacts are strongest among less-skilled and already-resident Mexican male migrants. Areas of very high concentration of foreign-born, low-skill Mexican workers clearly experience the largest impacts. For thirteen metropolitan areas for which this labor group constitutes 60 percent or more of the foreign-born population, a 20 percent increase in this group results in wage decline among this same group of 11.4 percent. Employment of the group is reduced by 2.4 percent. Native, low-skill females of Mexican ancestry experience a 1.3 percent wage decline and a 0.4 percent job displacement effect.[4]

Economic Adaptation and Social Mobility. Social integration depends among other things on economic advancement. *One quite optimistic analysis favorably compares wage growth for first, second, and third generation Mexican-origin men with that of native whites and blacks.*[5] The findings show improvements, especially by the third generation, in both educational attainment and economic mobility. Nevertheless, the educational attainment of Mexican-origin men remains the lowest of any ethnoracial group. Our above-cited research and a study in Los Angeles, suggest that the wages of Mexican-origin men are dragged down by the combination of the group's low educational levels and competition with others with very low educational levels. These disadvantages are likely to persist and possibly increase if the volume of unskilled, and especially unauthorized, migration from Mexico continues.[6]

Enclaves and Entrepreneurial Activity. Mexican-owned businesses exist throughout the southwest and are making a strong showing in southern California. Research is finding successful Mexican enclaves in, for example, Los Angeles fruit markets. In Chicago, our work on "The Little Village Study" shows that dense settlement patterns (economies of scale) are conducive to the emergence of informal, and ultimately, formal, economic activity that caters to the needs of other coethnics. Evidently, economies of scale can have both offsetting and positive effects (Rosenthal & Tienda 1997). Clearly, more research is needed to address the positive attributes of Mexican entrepreneurs and consumers.

Welfare Participation & Fiscal Costs

Presumably motivated by the belief that legal and unauthorized immigrants participate "too much" in public assistance programs, Congress passed provisions related to immigrants as part of the Personal Responsibility and Work Opportunity Reconciliation Act of 1996. This Act restricts the access of even legal immigrants to welfare. Accordingly, we performed analyses of the public assistance utilization of Mexican-born households.

Welfare Participation. *The empirical results indicate that Mexican-born households are no more likely to use welfare than either otherwise comparable native-born households of Mexican ancestry or otherwise comparable native-born households in general*. They are, however, more likely to participate than native whites, but less likely than native blacks. Moreover, recent cohorts from Mexico are less likely to use welfare than otherwise similar groups, whereas earlier cohorts are more likely users (Davies & Greenwood 1997).

There is a general consensus that relatively young and recently arrived Mexican-born migrants are not more prone to use public assistance than natives of similar socioeconomic characteristics. Yet, migrants' characteristics determine their eligibility for welfare and, to a large extent, their propensity to apply for means-tested income transfers.[7]

Unauthorized Migrants and Fiscal Costs. *Most studies agree that immigrants, and especially unauthorized migrants, impose a fiscal burden on state and local governments, but there is considerable disagreement about the magnitude of this burden.* In recent years, states have brought suit against the U.S. federal government to recover the costs of providing services to unauthorized migrants. At the national level, however, there is less consensus on costs that may not be fully resolved for several technical reasons. Despite the limits of fiscal impact studies, we prepared a secondary analysis of unauthorized migrants for California, Texas, and Illinois as an illustration.

Our calculations, using a *best estimate* of the unauthorized alien population, show that unauthorized migrants in California use $1,124 of state and local services per capita, which is higher than the $906 per capita used by the rest of the population. Public school expenses account for about two-thirds of these costs. In Texas, the unauthorized and the rest of the population *both* use somewhat more than $1,000 per capita in services. School costs account for more than 80 percent of these costs. In Illinois, unauthorized migrants use less state and local resources than the rest of the state population because of a comparatively older and smaller school population. The unauthorized in Illinois use relatively little in the way of state and local services.

California's total net fiscal burden of the unauthorized is the heaviest ($829 million) of all states, Texas's is much smaller ($194 million), and Illinois's is almost trivial ($17 million) relative to the state budget. These net figures are smaller than the states' estimates used in claims against the federal government because the states' costs (but not revenues) are based on figures for the unauthorized population that seem to be too high.[8]

There is no disagreement that California bears the brunt of immigration, including unauthorized migration. The fiscal impact of the state's many migrants is magnified by a relatively large per capita fiscal gap between the unauthorized and the rest of the population. This gap results from the higher rate and more progressive nature of the tax system in California, which leaves the unauthorized paying a smaller share of the total state and local tax burden.

A final caveat to these studies is that the fiscal impacts of migration that should concern us occur over the life span of migrants. In all static models to date, education is a cost. Yet, education is fundamentally an investment in future skills and earnings and we can reasonably expect that its current cost will be recovered in future greater productivity, especially if children complete school and become taxpayers. This expectation is born out by recent work by an expert National Research Council [NRC] (1997) panel.

Demographic Impacts

Contribution to Population Growth. Recent trends in immigration have left an indelible demographic imprint. From 1970 to 1990, *total* international migration accounted for 25 to 33 percent of net annual population increase. However, Mexican migration itself is only part of total immigration and contributed less (U.S. Bureau of the Census 1996). During the 1960s and 1970s, approximately 14 percent of all legal immigrants admitted were from Mexico. This share rose to 23 percent during the late 1980s owing to the impact of the legalization program. In FYs 1995 and 1996, Mexican-born immigrants were 12 and 18 percent respectively of total U.S. immigration.

Although Mexican migration has been a relatively small component of net aggregate population growth, its impact on the size of the Mexican-origin population is far more substantial. Migration was responsible for less than one-half (and substantially less for legal immigrants) of the growth of the Mexican-origin population between 1970 and 1980. At the latter date, only one in four persons of Mexican origin were foreign-born. By 1990, and in the wake of both the large volume of IRCA legalizations and continued migration from Mexico, more than one in three persons of Mexican origin were foreign-born (Greenwood & Tienda 1997).

Secondary (or indirect) demographic impacts derive from the fertility of native- and foreign-born women of Mexican origin. In 1990, the average number of children ever born to Mexican origin women aged 25 to 34 were 1.7 and 2.1 for the native and foreign-born, respectively. Among women aged 35 to 44, the nativity differentials in children ever born were greater still, 2.5 for U.S.-born women compared to 3.3 for Mexican-born women. Current and future demographic impacts, particularly those associated with the school-aged population and future workforce entrants, will be most pronounced in localities where Mexican migrants are concentrated. Female predomination in recent cohorts

(with the exception of the IRCA legalizations) has implications for the future demographic impacts of Mexican migration. For example, the median age of legal female Mexican immigrants in 1995 was 25, the peak of women's reproductive years.[12]

Population Projections. The U.S. Census Bureau estimates that the U.S. population will increase by 50 percent between 1995 and 2050, from 263 million to 394 million (U.S. Bureau of the Census 1996, 1997). Declining overall fertility and increased longevity mean that immigration will be a larger component of future growth. These projections do not separately identify immigrants, but we know that Mexicans comprise slightly more than 60 percent of all Hispanics, a share relatively stable since the early 1970s (Bean & Tienda 1987:Table 2.2). According to the Census Bureau's projections, the Hispanic population will contribute 37 percent of growth from 1995-2000, 44 percent from 2000-2020, and 62 percent thereafter. As a result, the absolute and relative sizes of Asian and Hispanic populations will more than double (rising from 5 to 8 percent of the total population for Asians and from 10 to 26 percent for Hispanics).[13]

A National Research Council panel (1997:26) made independent projections. The panel first estimated how large today's population would be in the absence of immigration since 1950. They concluded the U.S. population would have been 14 percent smaller than its 1995 size and would have been considerably older. Projecting forward current levels of immigration for fifty to fifty-five years would increase population by 80 million above what would occur without any immigration. This net increase reflects the direct result of 45 million new immigrants plus the dual indirect effects of higher immigrant fertility and a more youthful first- and second-generation immigrant population. As the single largest national origin group in recent years, Mexicans would account for approximately 10 - 12 percent of the increase at the base year, compounded by their higher fertility and young age structure.

Two important compositional changes follow from the current level and country of origin composition of immigrant streams. First, current immigration levels will increase future enrollments in primary, secondary, and college enrollments relative to lower immigration levels. Second, the race and ethnic composition of the United States population will change substantially with especially large proportions of Asians and Hispanics.

Social & Political Impacts

Social Relations and Status. In our study of social impacts, we address social status and the place of the Mexican-origin community relative to other ethnic and racial groups. It appears that Mexican migrants occupy some kind of intermediate social position between native whites and native blacks. Surveys indicate, for example, that all groups, including blacks, rate whites as the most desirable neighbors, blacks as the least desirable, and Hispanics in between. Whites in Los Angeles have been observed to be more opposed to housing integration with blacks than with Hispanics (in Los Angeles, Hispanics are almost entirely of Mexican origin). Other groups, such as Asians, seem to share the same preference for Mexicans over blacks as neighbors.

Let us be clear: Mexican immigrants do not occupy an intermediate social position because they are somehow middle class. On the contrary, that their social position seems higher than their relative socioeconomic status raises interesting questions about the significance of race and national origin, and suggests that Mexicans play a "buffer" role in the U.S. stratification system. And, the positive view of immigrants as neighbors may be explained, in part, by their role in revitalizing communities.[11]

Migrants and Crime. Relatively little research addresses the association between crime and migration. According to the 1991 Survey of State Prisons, Mexicans account for nearly half of the foreign born in state prisons. However, their overrepresentation may reflect differences in treatment through the criminal justice system. Migrants along the border are more likely to be arrested, detained prior to trial, convicted, and incarcerated (two to four times more likely) as citizens.[12] Unauthorized migrants also are less likely to be released from jail prior to trial.[13]

Voting and Political Impacts. Their neighborhood-building role in the inner city accords well with the reality or myth of the hardworking migrant, striving to get ahead. Survey work has shown that very few Mexican Americans believe that they have been victimized by racism or discrimination. Mexican Americans seem eager to embrace a meritocratic vision of American society. While Mexican Americans in the U.S. Congress tend to find common ground with black congressional leaders—both groups are predominantly Democratic, mostly urban, and largely progressive on fiscal issues—on the local level such black-Mexican coalitions have proved much harder to create or sustain.

The various political impacts of Mexican migration are felt primarily in *Mexican-American communities*. That most Mexican migrants cannot vote seems to imply

that no direct impact exists. Yet, the foreign-born affect electoral politics through census enumerations and decennial redistricting (congressional and state districts are based on all persons, not only adult citizens). Thus, Mexican-American districts have many fewer voters; in the 1992 United States elections, Mexican Americans cast only about 16 votes per hundred persons compared to 50 per hundred for non-Hispanic whites. While Mexican-born migrants increase the population base that creates Mexican-American districts, their disinterest in electoral politics, some argue, may dilute the natural bonds between elected officials and adult citizens.[14]

The Mexican-American community has increased its power in electoral politics since 1970 and the political impacts of Mexican migration—mediated through their relationship with Mexican-American communities—may have indirect effects on elections and legislation. In presidential politics, their concentration in California, Texas, and Illinois could give Mexican-American voters leverage, but only if the state in question were very closely contested. While Mexican-American voters have generally favored Democratic presidential candidates in proportions almost high enough to qualify as "bloc voting," their low turnout and fundraising potential means that national candidates have been likely to view them as marginal players. It remains to be seen whether or not the recent surge in the naturalization of Mexican-born adults, coupled with a political climate that might well cause new citizens concern, will affect these dynamics.

BORDER RELATIONS

Many of the impacts of Mexico to U.S. migration are experienced at the border itself and thus affect both countries.

Cross Border Commerce & Social Relations

Border communities are binational entities, with many residents on each side of the border having strong family, commercial and social connections to those on the other side. The volume of movements both ways across the long Mexican-United States border is substantial. The vast majority of border crossers go for short visits, often purchasing goods on the other side of the border. The contributions to local economies emanating from this cross-border commerce are also substantial.

The border relationship is not without its tensions, however. Cross-border petty crime, vandalism, and vice is a continuing source of concern in many border communities. Border cities complain about the fiscal impact when residents of the other country access such public services as health care and edu-

cation. The growth of poor, unincorporated areas that straddle the border presents challenges to public health and the environment. For the most part, however, the neighboring states, cities and townships have found it mutually beneficial to resolve tensions before they disrupt the important ties that bind the communities.

Violence en route to and at the border are among the most negative effects of migration between the two countries, largely but not exclusively related to the unauthorized movements. Migrants are victims of a variety of crimes, from attacks and abandonment by smugglers to theft, rape and even murder. Recorded and unrecorded deaths associated with attempted border crossings are of concern. So, too, are violent attacks by smugglers and others on officials who are responsible for border operations in both countries.

Human Rights Violations

Incidents of human rights abuses by federal, state, and local officials have been recorded as well. A well-publicized incident in Riverside, California, when local police were videotaped beating migrants after a high speed chase, highlighted the potential for such abuses. Both governments have taken action to curb the abuse of migrants by both private and official auspices on both sides of the border. Grupo Beta, for example, is a Mexican police unit charged with protecting migrants at the border itself. The recurrent allegations of abuse have led to the establishment of a number of monitoring groups, as well, including the Border Liaison Mechanism.

ENDNOTES

[1] According to U.S. data, 85 percent of Mexican-born persons are between 15 and 64 years of age; only 4.6 percent are 65 years and older (CPS 1995).

[2] The research literature repeatedly finds that migrants have only small national-level impacts on U.S. workers. Three reasons have been suggested: migrants are a small fraction of the labor force; offsetting effects occur in labor demand and supply relationships; and efficient U.S. markets may arbitrage the effects across the nation, making them difficult to detect. The first two reasons are most plausible. A large body of research on regional adjustments suggests that effects would not necessarily be rapidly "arbitraged" and large, direct impacts of new arrivals should be measurable.

[3] It is true that new migrants often work at lower than average wages that, in theory, reduce production costs for employers. However, this occurs mainly in labor-intensive, competitive industries with typically low-productivity and low-profit margins overall.

[4] The sectoral distribution of migrant labor ultimately determines the impact of migration on the wage rates of domestic unskilled labor. That dramatic differences exist in the regional concentration of migrants and in the interindustry distribution of migrants implies distinct effects across regions. Because of their sources and border entry points, unauthorized migrants may be even more concentrated than the legal migrants, and their impacts will be concentrated accordingly.

[5] Mexican migrants are disadvantaged relative to native blacks in terms of educational and language skills, yet in most states they have higher rates of labor force participation and lower unemployment rates. That the most economically and socially disadvantaged groups are not immigrants, but rather African-American, Native-American and Puerto Rican, suggests that Mexican migrants have a reasonable chance of adapting to U.S. labor market and society. This research also finds that the intergenerational changes in the wage structure take longer to play out for Mexicans than for other white migrant workers.

[6] This research effort also suggests that wage penalties for lack of fluency in English may have increased during the 1980s when returns to skills rose appreciably. This bodes ill for the pace of integration of Mexican migrants in the future (Trejo 1997). Exposure to other immigrants, not generational status, is the most powerful predictor of language maintenance. The forces for retaining Spanish in public and private settings is particularly high for Mexicans, not only because of the volume and concentration of recent flows, but also because Mexican Americans are less likely to migrate internally and more likely to reside in multigenerational households that include one or more foreign-born persons.

[7] For instance, Mexican migrants to the United States are characterized by low levels of educational attainment, large families, and poor English-language abilities. All these factors, among others, are generally found to be positively related with the level of welfare use.

[8] Considering that careful estimates of the unauthorized migrant population vary by as much as 15 percent or more, caution is necessary in drawing conclusions about state level fiscal impacts. The largest cost is of unauthorized migrants is primary and secondary education. In our "best estimate" only children who are foreign-born and unauthorized are counted. In our "citizen children" estimate we include the citizen children of unauthorized migrants. This change raises the unauthorized population by only 5 percent, but the unauthorized school-age population rises by 25 percent. In California, this increases the total cost of services by 18 percent and the net fiscal burden from $829 million to $1.08 billion. In our "states' estimate" we use the states' own estimates of the unauthorized population, which is considerably higher than the Census Bureau's high-end estimate for 1992. This increases California's unauthorized population by almost 50 percent. Nevertheless, both the "citizen children" and "states' estimate" yield similar aggregate fiscal impacts.

[9] The larger completed family sizes of Mexican immigrant women result from childbearing *after* migrating to the United States rather than initially entering the United States with larger families. This is contrary to predictions based on assimilation theory and differs from the fertility behavior of other immigrant women.

[10] The growth of the Mexican-origin population is likely to increase far more than the other Hispanic origin groups for several reasons. Mexicans are the largest source country of current immigration. Fertility of both native and foreign-born Mexican-origin women will likely contribute to relatively faster population growth. The 1995 Mexican-origin population is larger and relatively younger than other Hispanic origin groups, providing a bigger base from which to compound future indirect effects. Finally, Mexicans have been and are likely to remain the largest source of unauthorized migration.

[11] Research in Chicago's "Little Village" reveals that Mexican migration either contributes to community revitalization or prevents decaying inner city neighborhoods from

becoming underclass neighborhoods. From 1970 to 1990, Chicago experienced a tremendous polarization in neighborhoods inhabited by natives. By 1990, most of the neighborhoods that in 1970 were working class and stable middle class neighborhoods had either gentrified or been absorbed into black ghettos and abandoned by all but the poorest residents. The parts of Chicago in which working-class neighborhoods have grown or even been maintained are those areas settled by migrants—primarily Mexicans.

[12] Gross differences in the incarceration rates of Mexican and U.S. citizens disappear once differences in age structure (because Mexicans are younger and petty crime rates are higher among the young) and especially the differences in treatment in the criminal justice system of Mexicans and Anglos are taken into account (Hagan and Palloni 1996).

[13] Incorrect perceptions about criminality, nevertheless, contribute to what appears to be public misperceptions about immigrants generally. Especially during times of high unemployment and job competition, i.e., the changed climate of California in the late 1980s, public opinion is for reduced immigration. Surveys in 1995 found that Mexican-born migrants were the least preferred of any immigrant group. Several polls conducted during the 1990s found that respondents believed that two-thirds of migrants to the United States were unauthorized, an obvious impossibility, but partly an outcome of public leadership and discourse that continually blurs the line between illegal and legal immigrants.

[14] In turn, Mexican Americans seem to be ambivalent about new migrants from Mexico and, at times, at odds with the views of their leadership. Various surveys have found that Mexican Americans view unauthorized migration in particular very unfavorably. Perhaps this is associated with various election-day polls that found that as many as 30 percent of Mexican Americans voted for California's 1994 "Proposition 187," arguably one of the most egregious pieces of anti-immigrant legislation in the post-Civil Rights era.

VI. RESPONSES TO MIGRATION ISSUES

Societal responses on migration matters are manifested in the two countries in many ways. These include: legislation at the federal, state, and local levels; policies implemented at all these levels; decisions by the courts; advocacy from the private sector; and public opinion as reflected in polls and referenda.

To reach our overall conclusions, we draw upon the lengthy history of the two neighbors reaching back to the Bracero period and earlier. From this longer vantage, and with an eye toward today's events, our major conclusions are as follows.

- *Episodic nature of U.S. responses*. The debate on immigration into the United States waxes and wanes with the economic cycle. When the U.S. economy falters, restrictionist sentiment grows more intense. When the Mexican economy goes into a slump, this too leads to fear of an emigration push and anti-immigrant concern in the United States.

- *Unintended consequences.* Several important U.S. policy changes since 1965 have had unforeseen consequences often at variance with the policy intentions. One recent example is the growing immigrant visa backlog prompted by family unification requests stemming from the IRCA legalization provisions. The disjunction between policy intentions and actual outcomes has been a perennial feature of immigration history.

- *Mexican engagement*. The Mexican government has shifted from a position of deliberate nonengagement on migration matters to a stance of increasing dialogue with United States counterparts. The contrast is evident in Mexican unwillingness to comment when IRCA was under consideration compared with the Mexican authorities commentary regarding U.S. immigration and related legislation in 1996. The practical outcome of increased dialogue is still uncertain.

- *Interplay between economic integration/political cooperation and immigration control.* The bilateral engagement on migration began before NAFTA went into effect, but cooperation on this issue picked up after NAFTA facilitated a more elaborate framework for economic and political dialogue.

- *Border opening for commerce and investment but not people.* The flow of goods, services, capital, and the legal entry of people has been facili-

tated by NAFTA and other measures adopted in the 1990s. Simultaneously, the United States is increasing efforts to control unauthorized entries. This has the potential for increasing binational tensions.

- *Official action and ineffectiveness of immigration restriction in practice.* In the past, U.S. responses to deal with illegal immigration were riddled with loopholes or not carried out with vigor. It remains to be seen whether the current efforts will be more durable or will be pursued more seriously.

Analytical Model

Based on observation of migration responses, the following model was used as a basis of analysis:

- An underlying context, one usually rooted in the U.S. economic situation, triggers a U.S. immigration response;
- This, in turn, leads to a period of debate in the United States and political compromises resolve some differences but leave other issues on the table;
- A Mexican reaction to the U.S. action, and perhaps a U.S. counter-reaction follows;
- A new context for the next series of triggering events is thus born.

U.S. and Mexican responses also have a long-term trend: the intervals between the periodic debates has diminished.

Responses in the United States

United States responses to immigration are largely unilateral. This suits the U.S. style and had a practical logic when the Mexican authorities preferred not to be involved. This may now be changing, although to what extent is unclear.

Interest Group Influence. United States immigration responses usually are directed at immigration generally and sometimes Mexican immigration specifically. The U.S. has a diverse collection of politically active groups seeking to influence many aspects of policy and a long history of admitting large numbers of foreigners as permanent residents. Nongovernmental organizations, both

those favorable to increased immigration and others that support a more restrictive policy, play a large role in shaping U.S. immigration policies.

The political process translates these conflicting goals into policies that often have unanticipated outcomes. Given public opposition to increased legal immigration, the legalization provisions of IRCA in 1986 and the 1990 Immigration Act (both of which increased substantially the number of permanent legal residents admitted) were surprising. These outcomes stemmed from interest group influence on the legislation. In 1996, an effort to reduce certain categories of legal immigrants was unsuccessful, but new efforts are likely. Federal policy changes in the 1990s have reduced immigration backlogs, handled a quantum increase in naturalizations, and facilitated legal entries at the border through the use of commuter lanes and expedited preauthorized clearances.

State and Local Reactions. A less surprising development has been the government response to deter unauthorized immigration as manifested in IRCA and the rise in appropriations for border enforcement. Two other recent developments are the distinctions made between legal immigrants and U.S. citizens in their access to social services contained in the recent welfare legislation (the Personal Responsibility and Work Opportunity Reconciliation Act of 1996), and the expanding role played by state and local governments in (1) restricting services to immigrants (e.g., the passage of Proposition 187 in California) and (2) the discretion given to state governments in welfare payments to legal immigrants. Because migration effects are local, a greater effort to bring states and localities into migration policy discussions would be desirable.

Immigrants are concentrated in a small number of states and metropolitan areas and, consequently, state and local officials differ in their reactions to immigration. States and localities with large numbers of immigrants typically face higher public costs to provide education and other services than those with fewer immigrants. But there have been significant variations in the responses of states and local governments with large immigrant populations. Proposition 187 was actively supported by Governor Pete Wilson and other California public officials. It was promoted with arguments that underscored the view that denying public services to unauthorized immigrants would deter further illegal immigration. State and local officials elsewhere, e.g., the governor of Texas and the mayor of New York City, disagreed sharply with these views and tactics.

More on Public Opinion and Interest Groups. Despite the substantial public support beginning in the 1970s for penalizing employers who "knowingly" hired illegal aliens, employer sanctions were not adopted until 1986. However, the means to identify persons unlawfully in the United States were slipshod and the law, even as written, was not rigorously enforced. These compromises reflected different views of the many interest groups and public officials involved. Public opinion has been less supportive of legal immigration than Congress and more inclined toward strong measures to deter illegal immigration. Public opinion on immigration tracks reasonably well with local economic conditions: restrictionist views rise as the economy worsens. The correlation between growing unemployment and restrictionist sentiment shows up clearly in U.S. data for at least the last fifty years.

Generally, small-and-medium size businesses and fruit and vegetable growers in the southwest, especially California, favor increased immigration. They sought unsuccessfully to obtain a new temporary worker program in the last Congress. (They have not, however, supported an expansion of the existing H-2A program.) Agricultural growers of labor-intensive crops have had much success in the past in achieving their objectives in legislation, as the Special Agricultural Worker [SAW] and Replenishment Agricultural Worker [RAW] provisions of IRCA testify. Labor unions generally oppose substantial immigration. Mexican-origin persons legally resident in the United States are ambivalent and as likely to oppose as to favor large-scale immigration. There is no uniformity in the positions of similarly situated interest groups, but the broad outlines described above tend to prevail. Nongovernmental organizations [NGOs] vary in their views depending on their functions. There are anti-immigrant NGOs, pro-immigrant advocates, and others concerned with related issues, such as the protection of civil and human rights.

Many of the vocal interest groups have an ethnic orientation. At times, the immigration interests of one ethnic group conflict with those of others. For example, there is a large backlog of spouses and minor children of Mexicans legalized under IRCA, whereas the traditional backlog among legal Asian immigrants is more heavily weighted by siblings. Nevertheless, the NGOs of the two groups and their respective congressional caucuses have stuck together to fight against any reforms in legal immigration priorities. They have a common conviction that political empowerment is the best path for achieving their objectives, and this has led to a dramatic increase in citizenship applications of

immigrants legally in the United States. This particularly affects legal Mexican immigrants who, as a group, have heretofore been slow to naturalize.

The 1996 United States Legislation. The year 1996 was an active one for legislation concerning immigrants [see table VI.1]. The full extent of the legislation enacted in 1996 will not be apparent for many months. The new immigration legislation should be viewed in combination with two other laws passed in 1996, those dealing with welfare reform and antiterrorism. Some of the significant elements of these three laws (the Illegal Immigration Reform and Immigrant Responsibility Act, the Antiterrorism and Effective Death Penalty Act of 1996, and the Personal Responsibility and Work Opportunity Reconciliation Act of 1996, i.e., the Welfare Act), coupled with related policy actions taken by the INS are summarized below in Table VI-1.

U.S. Supreme Court decisions have shifted away from the initial presumption that immigration officers are bound by traditional fourth amendment requirements enunciated in cases such as *Almeida Sánchez v. U.S.* (1973), and *U.S. v. Brignoni Ponce* (1975). These more recent decisions have allowed the INS considerable discretion in the conduct of workplace enforcement activities (*INS v. Delgado*, 1984), and more recently suggested that the fourth amendment may not extend to all unauthorized aliens present in the United States (*U.S. v. Verdugo-Urquidez*, 1990).

Responses in Mexico

Migration is so prominent in Mexico's domestic and foreign affairs that a public stance is unavoidable. This need must be weighed against a long-standing tradition of noninterference in the domestic affairs of other countries. The way out of this dilemma has been to pursue certain objectives related to migration, but not to have a migration policy as such.

Major Objectives and Strategies. The Mexican government has pursued three major objectives over the recent decades: historically, and most prominent, the protection of the rights of emigrants; second, avoiding abrupt changes in U.S. immigration policy and in the flow of migrants; lately, in reaction to the recent negative U.S. climate against immigrants, seeking recognition for their contributions to the receiving society.

Until the mid-to-late 1980s, the Mexican government had a policy "to have no policy" on undocumented migration to the United States. This approach was

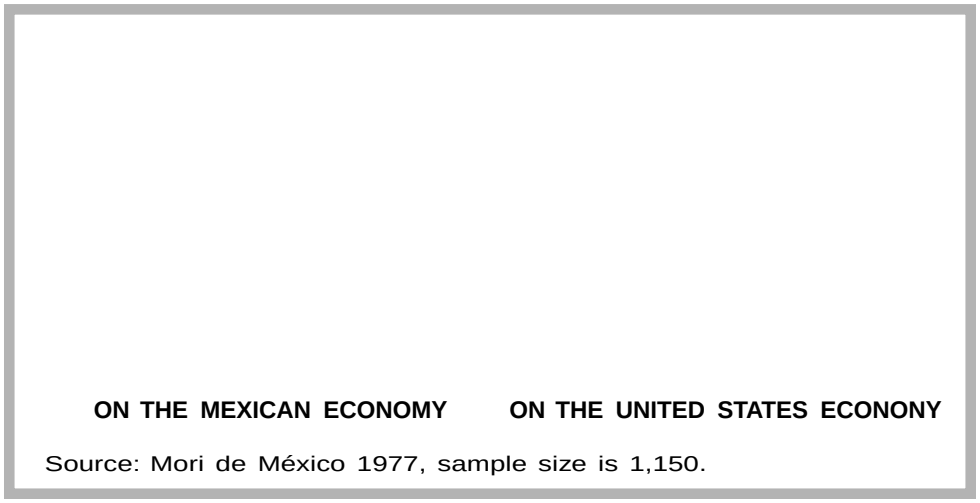
Table VI-1. 1996 Legislation Affecting Immigration

1. Number of border patrol officers increased annually for five years, a provision that has particular effect on illegal immigrants from Mexico.
2. New triple fencing installed between San Diego and Tijuana.
3. At same time, entry of legal immigrants and border crossers from Mexico facilitated.
4. Old border crossing cards removed, to be replaced with new card with a biometric.
5. Expedited removal is carried out without hearing of immigrants illegally in the U.S., unless there is a credible asylum claim or two-year presence.
6. Distinction between exclusion and deportation abolished.
7. New areas created for which administration decisions cannot be reviewed by the courts.
8. This includes lack of judicial review of final orders of deportation for most criminal aliens.
9. In addition, definition of “aggravated felony” is expanded even if imprisonment is suspended.
10. Certain legalization class action suits pending in courts are no longer subject to judicial review.
11. Standards for suspension of deportation (now "cancellation of removal") made more restrictive and burden of hardship increased from extreme to exceptional and extremely unusual hardship and harm must be to a U.S. citizen, legal permanent resident spouse, parent, or child.
12. Criminal penalties for immigration violations enhanced.
13. Legal immigrants barred from usage of supplemental security income [SSI] and food stamps until they obtain citizenship. (Proposals to ease some of these provisions are pending.)
14. Legal immigrants entering after enactment of Welfare Act barred for five years from most federal means-tested programs, including Medicaid.
15. Welfare reform amended to provide certain exemptions for battered spouses and immigrant children abandoned by parents.
16. Immigration affidavits of support raised to 125 percent of poverty level and made binding on sponsors until naturalization or forty quarters of employment by sponsored alien.
17. Aliens made inadmissible as legal immigrants for 3 years if illegally present in U.S. for 180 days to 1 year, for 10 years if present for 1 year or more, permanently if previously convicted of an aggravated felony; plus other grounds for inadmissibility.
18. Pilot programs to verify employment eligibility implemented.
19. Persons unlawfully in U.S. are not eligible for social security benefits or post-secondary education.
20. Attorney General permitted to enter into written agreements with state and local agencies to perform functions previously exclusive to federal immigration agents.

believed to suit the principle of mutual respect and recognition of both national sovereignties. This approach began to shift when Mexico started to liberalize its economy and play a more active role in world economic affairs, exemplified by entry into the General Agreement on Tariffs and Trade and closer engagement with the United States in NAFTA. The cooperation and consultation with the Commission for the Study of International Migration and Cooperative Economic Development (Asencio Commission) was an early signal of increased Mexican engagement with the United States on migration issues.

Mexican authorities now lobby in the United States on political and economic matters, which they did not do prior to the NAFTA negotiating process. The Mexican government no longer operates solely via its Secretariat for Foreign Relations [SRE] communicating with the U.S. Department of State, but rather fans out across the spectrum of U.S. private interest groups, public agencies, and the Congress. The increased closeness of the economic relationship and its salience for Mexican economic recovery and growth also means that it is important to handle other problems in a way that avoids prejudice to economic cooperation. On migration, it is worth noting the participation of the Secretariat for Government Affairs [Gobernación].

Public Perceptions. Mexican public opinion and the media have become quite sensitive and critical of the way the two governments respond to migration. U.S. measures tend to be perceived not only as anti-immigration, but also as unfair to immigrants. This perception derives in part from a broad belief that the U.S. benefits even more than Mexico from Mexican migration. [See figure VI-1.]



Source: Mori de México 1977, sample size is 1,150.

Figure VI-1. Perceptions about the Effects of Migration

Immigrant and Immigration Legislation. Immigrants and immigration legislation in Mexico have a radically different significance than in the United States. Immigrants in twentieth century Mexico have been few in number and of marginal demographic significance. Foreigners usually have come to Mexico with capital and skills and, therefore, have had an impact disproportionate to their numbers. At various times, Mexico has received sizeable number of refugees, most recently from Central America. Central Americans also come as temporary workers. Central Americans, among others, also use Mexican territory in their transit to the United States. Immigration legislation emphasizes family connections and employment skills as a basis for admission, but also confers great administrative discretion on Mexican officials.

Mexican law requires that nationals demonstrate at departure that they have permission of the receiving country to enter. This requirement has not been enforced and probably is not enforceable, especially when departures take place away from designated exit points. For several decades, Mexicans have interpreted the constitutional right to free transit within Mexico as extending to the right to leave the country. This interpretation has not been tested by the Mexican judiciary, but there is a national consensus that the Constitution forbids the government from stopping the departure of nationals from its territory.

A feature of Mexican immigration legislation is that it indicates goals and priorities without going into much detail. Mexican immigration law gives great administrative discretion to the executive branch to decide whether particular decisions are consistent with the overall policy goals. However, most recently in 1990, 1992, and 1996, immigration legislation has been modified to liberalize the entry of certain categories of foreigners, particularly to facilitate the entry of business visitors, investors, technicians, professionals, and others to conduct business in Mexico—under NAFTA, special facilities are given to American and Canadian businesspersons—but at the same time to strengthen the criminal penalties for the smuggling of human beings.

Responses to Mexican Communities Abroad. Through the years, a sizeable Mexican community—Mexican citizens and Mexican-origin population—has been created in the United States. To strengthen the links between migrants, recent or earlier, and their country of origin, as well as to support some of their demands, the Mexican government has developed various responses for these Mexican communities. Consular, cultural, and business activities have been expanded. One of the most recent responses has been to change the norms

regarding Mexican nationality. In December 1996, consti-tutional amendments were passed that when implemented will allow Mexicans to naturalize in another country and not automatically lose their Mexican nationality.

Current Context

The bilateral interaction on migration issues has altered in recent years from a lack of consultation to considerable discussion between the two governments. Negotiating NAFTA required a shift in bilateral political relations. Mexico's earlier reflexive opposition to U.S. international initiatives has given way to a more cooperative relationship. The United States gave political relations with Mexico a higher profile, and showed increased receptivity to Mexican overtures.

Economic-political contacts have been facilitated by embedding them in institutional arrangements. NAFTA created a number of such institutional arrangements and breathed new life into established consultation groups. The Working Group on Migration and Consular Affairs of the Binational Commission is the single most important body for consultation on migration matters. In May 1997, when President Clinton visited Mexico, the Working Group discussion dealt with the exchange of information on migration policies and legislation, consular protection, and increased cooperation at the border. The Joint Statement on Migration adopted by the two Presidents signals a commitment to enhance bilateral cooperation in the management of migration.

The bilateral engagement has led to a number of unilateral and cooperative actions. Fast lanes were set up to facilitate crossing into the United States. The wait to cross at San Ysidro was reduced from two hours to twenty minutes. Cooperation to prevent drug smuggling was increased at the border. Grupo Beta is a Mexican effort to make the border safer. Mexicans participate in the Citizens' Advisory Panel on the U.S. side. There is a joint Border Liaison Mechanism. Both sides took steps to reduce smuggling of immigrants.

Based on the premise that economic development is the best and only long-term strategy to deter mass migrations, NAFTA is seen as a way to stimulate development and thereby slow emigration through enhanced employment and higher wages.

Currently, goods and services can pass more or less freely across the Mexico-United States. border, as can capital—but not labor. NAFTA is a free-trade area, not a common market within which all factors can move freely. In the

buildup to the NAFTA negotiations, Mexico raised labor inclusion, but the U.S. rejected this on the grounds that the Congress would not accept it.

There are proposals from time to time for a U.S. guestworker program with Mexico for the admission of less-skilled workers. A modest temporary worker program exists between Canada and Mexico. Such proposals recently have been suggested by some groups on the Mexican side based on the premise of more equal treatment of all factors—labor as well as capital—on the inability of Mexico to control emigration. They have also been proposed by some groups in the United States based on their inability to seal the border and the desire of some employers to have ready access to legal-temporary workers..

Despite the increased dialogue, disagreement between the two countries on migration issues increased dramatically as a consequence of the 1996 U.S. enactment of legislation on immigration, welfare, and antiterrorism. All these laws will affect Mexican nationals. This increased tension came on top of the U.S. debate on whether to certify Mexico as cooperating with the United States in combating drug trafficking. This combination of problems—drugs on the one hand, migration on the other—set back the cooperative atmosphere that had been developing. Although the Clinton presidential visit sought to mitigate the conflict, it remains under the surface.

VII. CONCLUSIONS

Mexican migration to the United States is a long-standing phenomenon that remains complex and dynamic. In general terms, Mexicans in the United States fall into one of two migrant categories (sojourners or settlers) and in one of three legal conditions (unauthorized, legal immigrant, and naturalized citizen). Our results suggest that the total size of Mexican-born resident population in the United States in 1996 was 7.0 - 7.3 million persons. Of this population, legal residents accounted for about 4.7 - 4.9 million persons, about 0.5 million of whom were naturalized United States citizens. Unauthorized migrants accounted for 2.3 - 2.4 million persons. Estimates based on Mexican or U.S. data indicate an annual flow from 277,000 to 315,000 persons.

The characteristics of Mexican-born migrants differ systematically by migration pattern and legal status. This study demonstrates that, despite much continuity, the characteristics of migrants show increased diversity over time. Mexican-born migrants tend to have low skill levels, relative both to the U.S. population at large and to other migrant groups, although migration also absorbs a substantial portion of Mexico's skilled population. The low skill levels of most Mexican migrants reflect the demand for labor in sectors where Mexican-born migrants are employed and, in turn, are reflected in the low incomes and high poverty rates of Mexican born settlers in the United States. This situation is exacerbated by the unauthorized status of many of these migrants.

These changing characteristics are consistent with the increasingly diverse demand, supply, and network factors that are shaping migration flows. The catalyst for much of today's unauthorized Mexican migration for United States employment lies in the United States, but over time new factors have created a larger and more complex set of reasons that sustain the flow. The same tendencies that currently seem to be increasing and diversifying Mexico-United States migration flows may be dampened or reversed starting in the next five to fifteen years, reducing Mexico-United States migration.

There is substantial evidence of benefits to both the United States and Mexico from this migration, but the research also reveals costs to local communities and social sectors. Migration has repercussions through the labor market and supply and demand, through fiscal implications for national and local governments, and upon political and social institutions. In Mexico, the distribution of impacts are concentrated in a relatively small number of households, communities, and regions. The most important direct impact of migration is the income sent home

to Mexico by migrants in the United States (i.e., remittances). In terms of the remittance income they provide, migrants are Mexico's third leading export after oil and tourism and ahead of agriculture. In addition, migrant financing of new investments and reduced pressure for internal migration provide benefits. Given low productivity and low returns to labor in Mexico, migrants are an important source of income, investment capital, and income insurance. The negative impacts take the form of loss of human capital, as well as the social disruption that comes when families are separated.

In the United States, owners of capital, that is business owners and investors, as well as consumers, clearly benefit from Mexican migration. This benefit comes at a cost, however, to certain categories of workers, particularly already-resident migrants whose wages have fallen with the competition of new migrants. In areas where Mexican migrant concentrations are extremely high, such as in certain cities along the southwestern border, wage depression and job displacement effects are evident. For the average United States region, however, even relatively large increases in Mexican-born labor have relatively small impacts on native workers. With regard to fiscal impacts, Mexican migrants do present significant costs to certain states and localities. These costs do not derive from disproportionate use of welfare programs, however. The empirical results indicate that Mexican-born households are no more likely to use welfare than either otherwise comparable native-born households of Mexican ancestry or otherwise comparable native-born households in general. Mexican-born use of education is the greatest cost, but this can also be seen as an investment in the future.

Responses to Mexican migration have evolved over time, often reflecting economic cycles in the two countries. The unintended consequences of policy changes have been significant and often at variance with the intentions of those policies. One recent example is the growing immigrant visa backlog prompted by family unification requests stemming from the legalization provisions of IRCA. In recent years, there has been greater engagement on migration policy. The Mexican government has shifted from a position of deliberate nonengagement on migration matters based upon the principle of noninterference in the internal affairs of other countries, to a stance of increasing dialogue with U.S. counterparts on migration issues. The bilateral engagement on migration began before NAFTA went into effect, but cooperation on this issue picked up after NAFTA facilitated a more elaborate framework for economic and political dialogue. Simultaneously, the United States is increasing efforts to control unauthorized entries. This has the potential for increasing binational tensions.

Policy Implications

The study findings support an enhancement of institutionalized and forward looking consultative mechanisms to identify and develop mutually supportive policy options. Migration between Mexico and the United States is clearly a sensitive topic for both countries. Yet, finding effective ways to curb unauthorized migration that take into account both countries' commitment to foster human rights is essential. This topic requires, therefore, delicate management of the process that takes into account historical, demographic, economic, social, cultural, psychological, and political factors in both countries. Consistent with the greater dialogue and cooperation that has characterized United States-Mexico relations in recent years, and with the spirit of this study, it is important that both countries work together to explore policy options and initiatives that could be jointly undertaken to meet the needs of both countries and increase the information available about the migration phenomenon.

Although the catalyst for much of today's unauthorized Mexican migration is due to the attraction of United States jobs, demand, supply, and networks are all responsible for the continued migration and, thus, solutions are to be found in both countries. The United States and Mexican governments should jointly address the three factors that influence migration between Mexico and the United States—demand, supply, and networks. We have learned from past experience that a comprehensive approach is needed; addressing one of the factors will not achieve the desired results as long as other factors are present.

In recent years, the Working Group on Migration and Consular Affairs of the Binational Commission has proven to be an important and effective forum for frank discussion of various migration issues. These discussions, however, have generally focused on alleviating the effects of policy decisions rather than on potential future policies within each country and their implications on each country's migrant and/or resident populations. We envision that this group's work would be supplemented with more frequent and structured conversations to: explore policy options, scenarios, and alternatives to handle migration; identify prerequisites to change; and determine foreseeable implications of the continuation of the current situation.

More specifically, the study team presents the following agenda of policy issues that should be considered by the Binational Commission Working Group on Migration and Consular Affairs:

- **Determining the consequences of migration-related legislation adopted by each country.** Regular, joint monitoring programs could help identify the intended and unintended consequences of newly enacted migration legislation in a more timely fashion. In particular, study is needed on the trio of U.S. legislation passed in 1996 related to immigration: the Illegal Immigration Reform and Immigrant Responsibility Act of 1996 [IIRIRA]; the Anti-terrorism and Effective Death Penalty Act of 1996 [AEDPA]; and the Personal Responsibility and Work Opportunity Reconciliation Act of 1996 [Welfare Reform]. IIRIRA augmented border controls, required new pilot programs to test more secure forms of employment verification, clarified eligibility for public benefit programs, bars unauthorized residents from legal admission for three or ten years, and made sweeping changes in provisions for the removal of unauthorized migrants.

  Study is also needed on the implications of changes to the Mexican Constitution related to nationality. Constitutional amendments were adopted in December 1996 that will allow Mexicans to naturalize in the United States and other countries and not lose their Mexican nationality. Once implemented, this provision could have notable impacts on naturalization patterns in the United States, as well as on return migration of Mexicans who become U.S. citizens.

- **Determining how best to address the demand, supply, and network factors precipitating continued unauthorized movements.** As research shows that the majority of Mexican migrants are economically motivated, both governments should focus their attention on this issue. For example, the governments should assess the extent to which the demand of U.S. employers can be reduced through enhanced enforcement of labor standards, including wage and hour requirements, child labor prohibitions, sanctions against the knowing recruitment and hire of unauthorized workers, and bars on discrimination based on national origin or citizenship. Also to be assessed would be the extent to which the supply factors motivating Mexican migration can be addressed through enhanced domestic economic development.

  Means of reducing the efficacy of networks in promoting unauthorized movements also need attention. Networks have been strengthened in recent years through both the traditional contacts of relatives and

coworkers and new smuggling networks. Recent surveys find that many Mexican migrants attempting unauthorized entry into the United States now pay for "professional" assistance. Continued strong efforts by both governments against the smugglers could reduce these networks as well as the exploitation of the migrants that often occurs with smuggling.

These asssessments of ways to address the combined demand, supply and network factors should recognize that dependence on immigration/emigration varies widely. Certain United States industries, occupations, and areas are more reliant on Mexican-born workers than others, just as Mexican regions, states, and communities differ in their dependence on the U.S. labor market. It may make sense to develop different tools in addressing demand in industries in which the employment of Mexican migrants is a long-standing practice versus those that are beginning to hire unauthorized workers. Similarly, different approaches may be justified in traditional versus nontraditional sending and receiving areas.

- **Developing migration impact statements in both countries.** Migration is affected by more than immigration policy. Although the social and economic policies of the United States and Mexico historically have affected Mexico United States migration patterns, the U.S. and Mexico repeatedly have been surprised by the others' changes in policies that affect migration patterns. There often have been unintended consequences of policy and legislative decisions that potentially could be avoided or lessened through this type of mechanism. Migration impact statements, discussed during annual United States-Mexican consultations and throughout the year, might alleviate some of the impacts of such policies as land reform or trade policies and include some mid-to-long-range perspectives.

  This recommendation echoes that of the U.S. Commission for the Study of International Migration and Cooperative Economic Development in 1990. That Commission called for U.S. government migration impact statements to prevent the shock of unanticipated migration such as the Caribbean migration following U.S. government increase in support for U.S. sugar producers. The feedback on these issues brought back by the delegations to their respective governments could be a useful addition to the debate of each country as it considers changes in immigration laws or policies.

- **Encouraging and promoting binational research on issues that can best be resolved through joint data collection and analysis.** This study amply demonstrates the benefits of joint data collection and studies on demographics and economic and social impacts. Data limitations often constrained the teams' abilities to draw firm conclusions on many issues. The research findings were strengthened, however, by the ability to work on both sides of the border and compare various data sets. Combining the different techniques and perspectives of researchers from both countries further strengthened the research findings. The very changes in migration trends that this study has documented call for a continuing capacity and infrastructure to examine the issues raised in this report

  Many of the most pressing questions about Mexican migrants simply have no adequate answers without data that track the same individuals over time. Without such data we cannot fully answer whether or not, or how, work experience and new skills lead to significantly better earnings either on return to Mexico or in the United States; how English skills at entry and Mexican American communities shape English ability over time; and, importantly, how schooling and parents' status affect the progress of migrant children.

  More specifically, joint data collection and analysis would enhance understanding of demographic, economic, social, and political/civic trends in the two countries that affect migration. Cooperative efforts to collect data in a way that enables comparisons between the experiences of migrants and nonmigrants would greatly enhance the ability to report on the changing characteristics and impacts of those who move between the two countries. A fuller research agenda is included in Appendix A.

- **Identifying measures to accommodate, and even to facilitate, the demand for increased mobility between the two countries.** Surely the size of the Mexican born population legally in the U.S. alone creates a need for facilitated flows for family and commercial purposes. The process of deeper economic integration—in trade, finance and investment—also will increase the pressures to deal with the migration consequences of this process. The number of border crossings in the southwest already has grown in the last few years.

One issue for the Binational Commission to consider is the degree to which Mexico should be treated as a special case in U.S. immigration policy (and vice versa), particularly given the existence of NAFTA and the long-shared border. The U.S. and Mexico already have begun to take measures to facilitate legal entry at the border, such as special lanes for frequent crossers. Prescreening of the applicants permits identification of those who are not likely to abuse the speedier inspection process.

The U.S. and Mexico, with Canada, also negotiated special nonimmigrant categories under NAFTA that allow for eased entry of business visitors, investors, intracompany transferees, and professionals. Canadians and Mexicans with a baccalaureate degree or appropriate professional credentials or experience may enter under the special TN visa rather than the numerically limited H-1B visa used to admit professionals from other countries. A transitional limit of 5,500 TN visas for Mexicans expires in 2003. Thereafter, an unlimited number of professionals who otherwise qualify for entry will be admitted.

The growing economic integration of Mexico and the United States calls for continued, systematic analysis of further arrangements that will facilitate trade, investment, and commerce between the two countries by facilitating the movements of people as well. The various barriers to easing constraints on legal movements also need to be identified and addressed.

- **Identifying mechanisms that maximize the benefits and minimize the costs of migration between the two countries.** As noted above, the study team recognizes that it is to the benefit of both countries to work towards eliminating unauthorized migration, which creates costs to both countries and makes migrants vulnerable to exploitation. The longer-term trends that suggest that emigration pressures may lessen in the years ahead are encouraging. In the interim, Mexican and U.S. policies should seek to capitalize on the economic return to migration to stimulate economic development. A thorough review of policies to identify how efforts to maximize the short term benefits and minimize their costs could be used to reduce the longer term pressures for migration.

  From the sending communities perspective, considerations should be given to how to decrease costs of transferring remittances, encourage

their use for productive investments, and help migrants use their U.S. working experience more effectively towards an economic return in Mexico. The cost of transferring remittances is often 20 percent of the amount transferred, meaning that as much as $1 billion is lost to the migrants themselves. Targeting more resources to poorer areas by reducing transfer costs, particularly if combined with new strategies to encourage their most productive use, may be one of the best ways to reduce migration pressures in the long term.

On the United States side, a long-term strategy to reduce unauthorized migration should consider policies that facilitate legal entry for those who are qualified for nonimmigrant and immigrant visas. The U.S. also should assess whether recently adopted policies are undermining the productive value of legal immigrants by withdrawing their eligibility for benefits when they are in need. The U.S. as well should consider how a more vigorous enforcement of labor standards could ensure that workers are paid full wages and work in humane conditions. Further, it should be recognized that excluding unauthorized children from school and basic health care may ultimately create larger costs for the society at large without substantially reducing the unauthorized flows. Both countries also should seek ways to facilitate transfer of school and health records as migrant children move from one country to the other.

- **Analyzing the advisability of a bilateral United States-Mexico foreign worker program, with due recognition that such a program is unlikely to be an effective remedy to unauthorized migration.** Perceptions in the United States and Mexico often differ widely regarding the ability of a temporary worker program to serve as a remedy for unauthorized Mexico-United States migration. We believe that the U.S. and Mexico should study the temporary worker idea very carefully to dispel myths about what might be involved in launching a new temporary worker program. Such a study is likely to puncture the notion that both sides easily could reach agreement on a truly binational program.

  While there is still employer demand for Mexican workers, there are few “certifiable” labor shortages in the U.S. industries, occupations, and areas in which Mexican and other nonimmigrant workers are employed. In some of these immigrant labor markets, real wages have declined and

work-related benefits have disappeared. Certification of the jobs currently filled by foreign workers is often the subject of litigation, and the use of legal nonimmigrant workers in these jobs may become more contentious as welfare reform augments the supply of unskilled U.S. workers. There also may be less seasonality in many of the labor markets in which Mexican-born workers are employed than is assumed, making it difficult to expect or enforce worker rotation.

Moreover, history has shown that U.S.-sanctioned Bracero recruitment in the 1950s oriented many Mexican workers toward the U.S. labor market instead of toward local jobs and development. This began a tradition of migration, raised expectations, and set into place a baseline of individuals and families who would eventually reside permanently in the U.S. Although meant to be a temporary supply of workers, one unintended consequence was to create a resident population. Many have argued that a "temporary" nonimmigrant program would not be temporary and would lead to an increase in permanent residents. If temporary workers in the United States were to come from nontraditional migration areas in Mexico, new migration streams might be set in motion.

Today, when Mexico is modernizing its economy and promoting export oriented economic development, a Bracero program might make investors reluctant to invest in areas from which migrants leave for the United States, thus reinforcing migrants' dependence on emigration. There is as yet no convincing evidence that U.S. border and interior control efforts have reduced unauthorized Mexico-United States migration, so that opening a legal channel for Mexican temporary workers would probably add to, rather than substitute for, unauthorized workers, perhaps depressing conditions for legal Mexican-born workers in the U.S. labor market. Indeed, the Special Agricultural Worker program [SAW] legislated in IRCA had that effect. Even though hundreds of thousands of farmworkers received legal status, agricultural growers continued to hire unauthorized labor.

Finally, various temporary worker proposals voted upon by Congress in 1996 had little in the way of protections for either United States or Mexican workers . For example, the proposed legislation would have weakened recruitment, wage, and housing requirements in current

farmworker programs. Also, 25 percent of the worker's wages would be withheld in a trust fund to be paid upon return—but only to the extent that the funds were not needed to cover health care costs associated with the temporary worker program. Such programs may "substitute legal for illegal workers," but it is not in the interest of either country to codify easily exploitable labor exchanges.

- **Addressing the social costs of migration, particularly regarding the separation and breakup of families.** Although there are not a great many studies on this issue, the information that does exist provides sufficient evidence that this is a serious issue needing attention. Migration too frequently has broken up families and left behind women and children and also lead children hoping for success as a migrant to leave their homes at a young age. Attention should be given to ways to alleviate the disruption/separation of families and the local economy and other social costs imposed by the migration. For example, the United States could seek ways to strengthen the family unit by eliminating the backlog of spouses and minor children awaiting family reunification (most of whom are Mexican). Further, the two governments could explore ways to identify and obtain support for families, mostly female headed, who have been deserted by migrating husbands/fathers.

APPENDICES
A. Agenda for Future Research

The binational team's agenda for future research includes studies of:

- **Demographic** issues, including the causes and consequences of differential fertility of Mexican-origin women in the United States and adjustment of their fertility behavior over time; the effects of intermarriage patterns on the assimilation of the Mexican-origin population; and the consequences of differential internal migration patterns by Mexican-born and United States born counterparts. Particular focus also is needed on Mexican immigration trends overall, as well as on: the demographic impacts of the IRCA legalization in both countries; the foreign-born populations' legal composition; modeling transitions among legal statuses; return migration, via surveys of relatives who emigrated from the U.S.; and migration-related interregional demographic changes in Mexico.

- **Economic** issues, including: whether capital and labor behave as substitutes and/or as complements; the scale effects resulting from concentrations of Mexican migrants in the United States; the reasons for the negative impacts of recent migrants on employment and earnings of earlier migrants; benefits and costs of migrants to particular industries and sectors of the economy; changes in welfare participation and levels of welfare based on duration of residence; the short and long-run fiscal impacts of legal and undocumented migrants from Mexico at the local, state, and national levels; the effects of NAFTA and other economic developments in Mexico on migration patterns and trends; Mexico's economic absorption of immigrants from other countries, including the degree to which new jobs generated in Mexico are taken by immigrants from other countries; better and more consistent estimates of costs of education, health, and social infrastructure related to migrants; the economic impacts of migration in nontraditional sending communities; the extent to which Mexican migrants working in the United States gain skills and capabilities that produce increasing benefits upon return; the contributions of remittances; the effectiveness of particular economic development strategies and programs on reducing migration pressures; and the relation between intensity of migration flow from communities and their economic and social performances over time.

- **Social** issues, including: the educational gains of the Mexican-born and their offspring compared to other immigrant groups; linguistic assimi-

lation of the Mexican-born population and the implications of Spanish language maintenance; possible bias against female sponsors in the new sponsorship requirements in the U.S.; the impacts and costs of migration to family, culture, and community in Mexico; and Mexico's social absorption of immigrants from other countries.

- **Civic and Legal Rights** issues, including Mexican immigrants' decisions on whether or not to naturalize; human rights violations of Mexican migrants en route and in the United States and of third-country nationals transiting Mexico; the main obstacles to correcting human rights violations in both countries; and the advocacy efforts of industry, agricultural, environmental, human rights, ethic, and other groups on immigration legislation.

B. Migrant Occupations, United States Labor Demand, & Border Crossers

There appear to be substantial changes occurring in the U.S. occupations of migrants since 1988. There are notable gender differences in occupation. For example, Mexican-born male migrants appear to have shifted out of agriculture to some degree from 1988 to 1997 and into manufacturing occupations. Women migrants, however, remain unlikely to have been employed in agriculture and women are more likely than men to work in manufacturing and increasingly likely to find employment in service occupations.

These observations are based on the following graphs that draw upon questionnaires systematically administered from September 1988 to the present. The surveys were done in the cities of Tijuana, Mexicali, Ciudad Juárez, Nuevo Laredo, and Matamoros. Unauthorized migration through Tijuana alone makes up an estimated 50 percent of the total flow from Mexico to the United States.

To determine the occupations in which migrants worked, the following questions were asked:

(1) Have you had a job in the United States?
(2) When did you leave your last job in the United States?
(3) What type of occupation did your last job involve?

Acknowledgements

The Mexico/United States Binational Study on Migration was a joint effort undertaken by twenty scholars from both countries who worked together in teams on five separate subject areas. The subject areas and team members are listed below. These researchers wrote background research papers and individual team reports, whose information and conclusions were collaboratively condensed and compiled into a joint summary report published under the title *The Binational Study on Migration Between Mexico and the United States*. The present three-volume publication contains the individual team reports (Volume 1) and background research papers and materials (Volumes 2 and 3) that were prepared as part of the Binational Study and that constitute the basis for the joint summary. We are appreciative of the efforts of the team members who, despite their different academic disciplines and subject area expertise, worked in a productive and collegial atmosphere. The summary report, the team reports, and the background papers all demonstrate the commitment of the binational members to producing a state-of-the art assessment of many aspects of Mexico-to-United States migration.

The Binational Study was funded by both the Mexican and United States governments in conjunction with private sector funding in both countries. This

structure was created to optimize the independence of the research teams and to make the final summary report immediately available to institutions interested in the critical role of migration in the bilateral relationship. The Mexican Ministry of Foreign Affairs funded the Study and, with the Ministry of Interior, supported the work of this Study. The U.S. Congress appropriated funds coordinated by the U.S. Commission on Immigration Reform, and both the U.S. Immigration and Naturalization Service and the Department of State made contributions. We also acknowledge funding received from the Consejo Nacional de Ciencia y Tecnología and the United States Information Service in Mexico. Private sector funders were very interested in the project. The Fundación Muguel Alemán in Mexico contributed and the Ford and the Hewlett Foundations in the United States also supported the entire project.

We are grateful for the data and information supplied to the Binational Study by government institutions in Mexico and the United States. We also appreciate the commissioned analyses prepared by Mexican and American consultants to the Study.

Finally, we acknowledge the many individuals in both countries who gave of their time and assisted the Study in gaining invaluable insights above and beyond the more mundane aspects of academic research. The Binational Study alternated its meeting sites between Mexico and the United States and visited several communities in both countries. Government officials were forthcoming in sharing information and hosting opportunities to learn in Mexico City, San Diego, Tijuana, Oaxaca, Washington, San Antonio, and Chicago. The members of the Binational Study especially appreciated the frank exchanges with community residents and migrants in Tijuana, Oaxaca, Guadalajara, and Chicago.

The publication of the present three-volume set did not occur before the U.S. Commission on Immigration Reform sunset on December 31, 1997. Publication was thus subsequently undertaken by the Mexican Migration and Policy Program of The University of Texas at Austin, a joint program of the Lyndon B. Johnson School of Public Affairs and the Population Research Center, under the supervision of Frank D. Bean. The three volumes and the joint summary are also currently available electronically from *http://www.utexas.edu/lbj/uscir*. Special thanks are owed to Anne Isenhower, without whose Herculean and well-organized efforts this project would not have been completed. José A. Arréllaga Acosta, Maria McGivney Arréllaga, Marlena Crusere, Eve Kleinman, Raquel Marquez, Nancy Meredith, Terry Sherrell, and Ruth Whitenton also provided valuable assistance. Other members of the staff of both the LBJ School and the Population Research Center also helped in the publication of these volumes, for which the Binational Study wishes to express its gratitude.

The Quantification of Migration between Mexico and the United States

Frank D. Bean, Rodolfo Corona, Rodolfo Tuirán & Karen A. Woodrow-Lafield

The migration of Mexicans to the United States is a complex phenomenon, with a long history and structural roots on both sides of the border. Not surprisingly, Mexico and the United States have often held dissimilar views of this migration. On each side of the border, government officials, policy specialists and the public have often revealed distinct perceptions as to the nature, magnitude, causes and consequences of the movement of persons between the two nations. This complicates the task of the analyst. This report seeks to simplify analysis by focusing only on the question of the quantity of migration. How large is the flow and what is the sizes of the populations in the two countries that result from it? These are among the most often discussed aspects of migration, ones that lend themselves to intense speculation. In Mexico and the United States, the question of numbers arises frequently as part of the public debate on migration, and analyses of the causes and impacts of migration in both countries depend, to a considerable extent, on the calculations (well founded or not) about the size of the phenomenon.

One of the first conclusions of this report is that Mexican migrants to the United States are not homogeneous, but rather consist of diverse subgroups that migrate

for different reasons (Bean, et al., 1994; Corona, 1993). Distinguishing among migrants is necessary in order to demarcate flows conceptually and in order to interpret the results of efforts to measure them. Recognizing differences among migrants also helps to evaluate the impacts of migration on the societies of origin and destination. From the outset, the question of the magnitude of immigration, therefore, has facets that imply a number of subquestions. How many Mexicans (authorized and unauthorized) are located at any given time in the United States? Of these, how many habitually reside in that country? How many work or look for work in the United States but actually live in Mexico? How many Mexicans enter the United States annually to reside in that country or to work in it? How many return within the same time period? What is the net flow, or the difference between the total entries and the total return flows?

Researchers trying to answer such questions on international migration are confronted with diverse methodological and technical problems. Besides the problems confronting efforts to quantify migratory flows that are well-known, other problems arise from the special characteristics of the movement of Mexicans to the United States. Analysis is difficult because of the surreptitious nature of much of the flow, the constant change in the nature of migratory populations, the difficulties in determining how long Mexicans stay in the United States, and the difficulties in estimating the considerable size of return flows to Mexico (even after lengthy periods of residency in the United States). This report seeks to overcome these difficulties insofar as possible. Its two main objectives are (1) to assess the results and adequacy of efforts of the past 25 years to estimate the magnitude of migration between Mexico and the United States, and (2) to develop estimates of the stocks and flows of migrants between the two countries circa the mid-1990s, based on the approaches and results of earlier assessments as well as on newly available data and research conducted in the 1990s.

Before proceeding further, two additional comments are in order. The first concerns terminology. We use the term “unauthorized migrant” throughout this report to refer to those Mexican migrants who are in the United States without authorization at a given point in time, either because they have surreptitiously entered the country or because they overstayed their legally authorized periods of stay. We are aware that many observers prefer other terms. Our choice of nomenclature is based on our conclusion that the term “unauthorized migrant” most accurately describes the category of persons who are not in the United States legally. We use the term migrant rather than immigrant because many of the persons in this category enter the United States for temporary purposes, that is they stay only short periods of time.

The second matter concerns the consequences of the Immigration Reform and Control Act (IRCA) of 1986 for Mexican migration flows. This legislation has had

such profound implications for the numbers and kinds of Mexican migrants going back and forth between Mexico and the United States that we wish to signal and underscore the importance of IRCA for our topic at the outset of this report. In almost every one of our discussions, we will be noting not only the ways in which we endeavor to measure the stocks and flows of migrants, but also the ways in which IRCA has influenced their magnitude. And because IRCA's legalization provisions have so increased the numbers of persons eligible for immigrant visas under the current provisions of U.S. immigration law, IRCA will also have implications for immigration flows in the future, as we note below.

The rest of this report is divided into six sections. We first consider the recent sizes of the total Mexican-origin and Mexican-born populations in the United States. Second, we discuss estimates of legal immigration from Mexico to the United States. Third, we examine estimates of unauthorized migration to the United States that are based mostly on U.S. data. Fourth, we present estimates of migration from Mexico to the United States that are based on recent data collected in Mexico. Fifth, we examine the available evidence about the migration to Mexico of persons from the United States and other countries. Sixth, we summarize and synthesize the results from the above sections, together with other recent data, to develop what we think are reasonable numbers as to the magnitude of the stock and flows of Mexican migrants to the United States just after the middle of the decade of the 1990s.

The Total Mexican-origin Population in the United States

The Mexican-origin population living in the United States has grown substantially during the 20th Century. The population consists of several groups with different experiences. First, there are those individuals born in the United States who can trace their ancestry to Mexico. This group in turn consists of those persons whose ancestors lived in those parts of the United States that once were part of Mexico, as well as those persons whose ancestors migrated to the what is now the United States. Second, there are those individuals born in Mexico who have subsequently moved to the United States. This group in turn can be broken down into three sub-groups—naturalized citizens, legal immigrants and unauthorized migrants from Mexico. The following discussion examines the size and growth of the total Mexican-origin population living in the United States, focusing on changes in the size of each of these components where possible. Our major purpose here is *not* to examine the estimates of these components in detail, because we undertake that exercise below. Rather, it is to demonstrate the rough size of the migration components in relation to the total. We begin by examining

changes in the way this group has been measured over time. Since the United States Census is the primary source of this information, we focus first on changes in census definitions. Then, we discuss the patterns of growth in the Mexican-origin population over the past century.

"Ethnicity" denotes a social identity deriving from group membership based on common race, religion, language, national origin, or some combination of these factors (Bean and Tienda, 1987:38). In part because ethnicity is a multi-dimensional concept, the way in which the Mexican-origin population has been defined by the United States Census Bureau has changed over the years in part because measurements have been based on a number of different indicators at different points in time (see Table 1). Prior to 1970, Mexican ethnicity could be operationalized through the use of various objective markers, including place of birth, parents' place of birth, language and Spanish surname. While serving to identify well Mexican-origin persons who were either foreign born or whose parents were born in Mexico, these identifiers failed to identify adequately third or higher generation Mexican-origin persons, especially those who no longer spoke Spanish at home or who no longer had a Spanish surname due to intermarriage. These limitations were especially problematic for identifying the Mexican-origin population given the group's long history in the United States. In response to

Table 1

[1] Only available for five southwestern states.

[2] Available for 25% of the foreign-born population

these concerns, a new measure of ethnicity was added to the 1970 Census in which Mexican ethnicity could be identified through the use of a subjective item, Spanish origin. The census measure on Spanish origin allowed respondents of any generation to identify themselves as possessing Mexican or several other Spanish-origin ethnicities.

Such changes in the basis for measuring the Mexican-origin population of the United States do not mask the fact that the Mexican-origin population has grown steadily over the last several decades (Table 2). Some of this growth can be attributed to natural increase in the U.S.-born Mexican-origin population. Mexican-American fertility rates are approximately 35 to 40 percent higher than those of Anglos (Bean and Tienda, 1987; Bachu, 1995; Clark and Ventura, 1994), while each of these groups appears to experience comparable mortality rates. Thus, even in the absence of migration, the share the Mexican-origin population contributes to

Table 2
Total Mexican-origin Population in the United States: 1900-1996

Year	Total Mexican-origin Population (in Thousands)	Percent of Total U.S. Population
1996	18,039 [1]	6.8
1990	13,393	5.4
1980	8,740	3.9
1970	4,532	2.2
1960	1,736 [2]	1.0
1950	1,346	0.9
1940	1,077	0.8
1930	1,423	1.2
1920	740	0.7
1910	385	0.4

[2] Mexican-origin population calculated as a sum of the Mexican-born population and natives of Mexican parentage.

growth in the total population would increase relative to the share contributed by the Anglo population.

The present day size of the Mexican-origin population in the United States, however, is mostly attributable to immigration from Mexico during the 20th Century. Corona (1994) and Edmonston and Passel (1994) estimate that the Mexican-origin population in 1990 would only have been 12-14 percent of its current size had there been no immigration from Mexico since 1900. Table 3 presents the size of the Mexican-born population in the United States for each decade of the 20th Century. The flow of immigrants from Mexico has fluctuated substantially throughout this period, but it is clear that the Mexican-born population has become over time an increasingly large component of the foreign-born population of the United States.

The growth of the Mexican-born population in the United States has varied as a consequence of economic and political conditions on both sides of the border

Table 3
Total Mexican-born Population in the United States: 1900-1996

Year	Mexican-born Population (in Thousands)	Percent of the Total Foreign-born	Percent of the Total Mexican-origin Population
1996	6,679 [1]	27.2	37.0

(Freeman and Bean, 1997; Szekeley and de la Garza, 1997). The border between Mexico and the United States attained its modern definition in 1848, but records on the Mexican immigration to the United States were not kept until 1908. The accuracy of such data is dubious, however, as the border region at that time was largely unsupervised and the nature of immigration from Mexico at the very beginning of the 20th Century is unknown. Two of the border states (Arizona and New Mexico) were only territories under U.S. supervision until 1912. The first large scale officially measured immigration from Mexico into U.S. territory occurred between 1910 and 1919. Increased demands for labor brought about by the exclusion of Chinese workers in 1882, Japanese workers in 1907 and a shortage of European immigrants during World War I encouraged Mexican migration. Numbers of Mexican migrants continued to increase as the federal government exempted the Western Hemisphere from the national quota laws of the 1920s and early 1930s in the name of Pan Americanism which was also encouraged by many in the southwest who looked towards Mexico for cheap labor (Reimers, 1992). However, when the demand for labor decreased during the Great Depression of the 1930s, The United States repatriated many Mexican-origin individuals. Many of those sent involuntarily to Mexico were American-born children.

Levels of migration from Mexico once again increased with the introduction of the Bracero Program from 1943-1964 (Figure 1). Starting in World War II, non-Mexican farm workers in California sought higher paying jobs in the defense

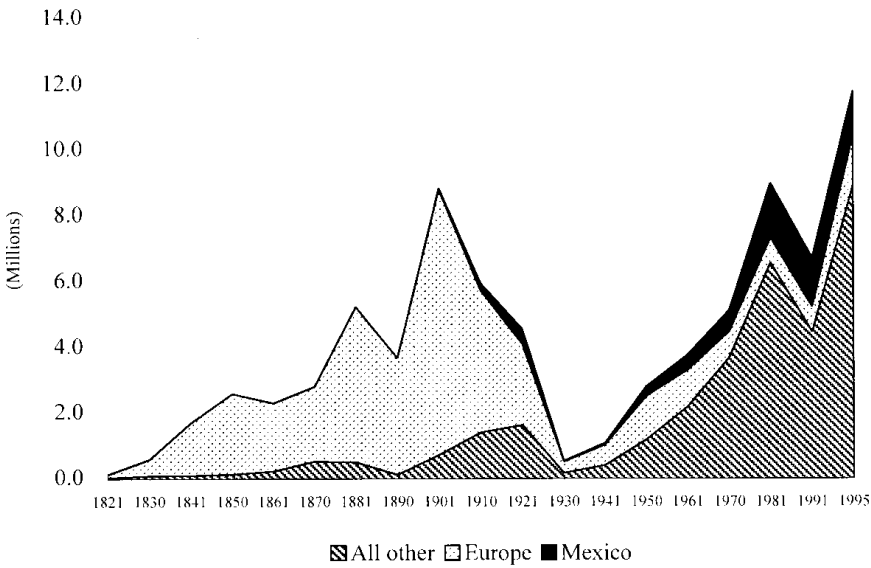

Figure 1. Legal Immigrants Admitted from Mexico, Europe and Total, 1821-1994

industry, reducing the available labor supply for farmers. This prompted growers to place pressure on Congress to admit temporary workers, or *braceros*, from Mexico. During the peak of the program in 1956, the number of workers recruited was 445,197 (Reimers, 1992). Although these workers were expected to be temporary residents in the United States, many stayed along with their family members. While growers fought to retain the supply of cheap Mexican labor, Congress refused to extend the program beyond 1964.

Despite the end of the Bracero Program, both unauthorized and legal migration from Mexico has continued to grow during the past three decades (Figure 2). In particular, the size of the legal population increased dramatically during the late 1980s and early 1990s, in part due to the legalization provisions of the 1986 Immigration Reform and Control Act (IRCA). Between 1989 and 1994, IRCA offered legal status to approximately 2 million undocumented Mexican migrants who had been either working in agriculture or living illegally in the United States before 1982. Table 4 illustrates the effect of IRCA's legalization programs on the size of the flow of immigrants from Mexico. When those legalizing their status under the amnesty provisions are removed from the official numbers of immigrants arriving in the decade, the size of the Mexican migrant population entering between 1981 and 1994 is greatly reduced. Another segment of the Mexican-born population in the United States is the unauthorized migrant population. We discuss below in

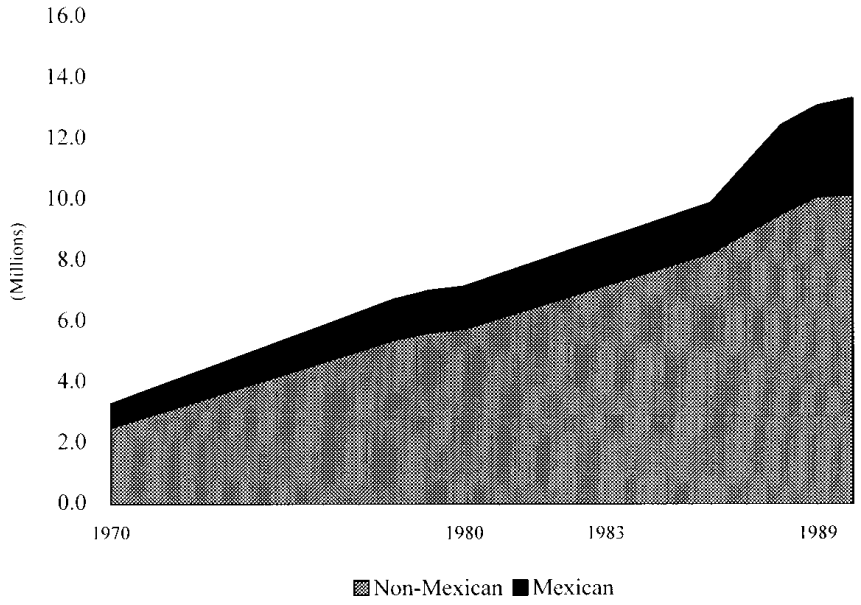

Figure 2. Legally Resident Foreign-born by Mexican Birth: 1970-1990

considerable detail estimates of the size of the unauthorized Mexican migrant population and the methods used to arrive at these estimates

Another component of the Mexican-born population in the United States includes those immigrants who have become citizens of the United States. Table 5 presents the numbers of Mexican-born persons who have naturalized over the past 35 years. Compared to other immigrant groups in the United States, Mexican immigrants have been slow to naturalize (Grebler, 1966; Bean and Tienda, 1987). English language ability is frequently cited as the largest barrier to citizenship among Mexican immigrants (Reimers, 1992). It is clear from Table 5 that the proportion of persons from Mexico who are naturalizing in any given year relative to the total Mexican-born population has increased over time. During 1996 the

Table 5
Number of Naturalizations among Mexican-born Persons in the United States: 1950–1996

Year	Number of Naturalizations Among Mexicans	Number per 10,000 Mexican-born Persons In the United States
1995	67,238	110.9
1990	17,564	40.9
1980	9,341	4.2
1970	6,195	0.8
1960	5,913	1.0

Source: U.S. Immigration and Naturalization Service (1996).

number of immigrants becoming citizens increased substantially as those legalizing their status under IRCA become eligible for naturalization, and as permanent resident aliens seek to attain citizenship in order to be eligible for benefits as required by legislation passed in the 104th Congress (U.S. Immigration and Naturalization Service, 1997).

Growth in the Mexican-origin population in the United States is expected to continue into the next century due to both natural increase and increased net immigration. According to Census Bureau population projections, the Hispanic-origin population will add more people to the population in the next 60 years than all other racial and ethnic groups combined (Day, 1995). Table 6 presents projections of the size of the Hispanic-origin population based on U.S. Census projections. These projections assume that the Hispanic population will receive the highest number of immigrants than any other racial/ethnic group (350,000 annually). In addition, the Census Bureau projections are based on the assumption that the higher fertility rates of the Hispanic-origin population compared to other groups will persist. Fertility in the Hispanic-origin population is matched only by the Asian-origin population in the United States.

The projections indicate that the Hispanic-origin population will make up approximately 25 percent of the population by 2050 (Day, 1995). The last two columns of Table 6 present the population projection for just the Mexican-origin population based on its size relative to the Hispanic-origin population. Two projections are presented based on slightly different assumptions. The first is based on the assumption that the relative size of the Mexican-origin population as a segment

Table 6
Projected Size of the Mexican-origin Population in the United States: 1995–2040

Year	Projected Size (in Thousands) for the: Hispanic Population	Mexican Population (Estimate 1)[1]	Mexican Population (Estimate 2)[2]
1995	26,936	16,135	16,337
2000	31,366	18,788	19259
2010	41,139	24,642	25,876
2020	52,652	31,539	33,908
2030	65,570	39,276	43,211
2040	80,164	48,018	54,031

Source: Projection of the Hispanic Population from Day, Jennifer Cheeseman, *Population Projections of the United States by Age, Sex, Race and Hispanic Origin: 1995 to 2050*. U.S. Bureau of the Census, Current Population Reports, pp. 25-1130, U.S. Government Printing Office, Washington, D.C., 1996.

Projection of the Mexican-origin population constructed by the authors.

[1] Assuming that the proportion of the Hispanic population that is of Mexican origin remains the same as observed in 1990 (59.9%).

[2] Assuming the Mexican-origin population will continue to increase as a proportion of the total Hispanic population by 1.5 percentage points per decade.

of the total Hispanic-origin population in the United States will stay the same. The Mexican-origin population represented roughly 60 percent of the Hispanic-origin population in 1990. Table 6 also presents a projection assuming that the Mexican-origin population will continue to increase as a proportion of the Hispanic-origin population over the next several decades. Based on these assumptions, the Mexican-origin population in the United States will more than double in size over the next sixty years. In fact, using these projections, the Mexican-origin population alone will be larger than the projected size of the Black population by the year 2050.

The projections make it clear that the Mexican-origin population in the United States will continue to increase for some time based on the characteristics of the population as of 1990. In addition, there are other ways that the Mexican-origin population can change in the near future without changes in fertility or mortality. For example, as those who legalized under IRCA become eligible for citizenship in the United States, they will also be eligible to petition to bring family members

to this country (Immigration and Naturalization Service, 1992). Mexican immigrants have the largest pool of relatives who could become migrants to the United States under the family reunification provisions than any other foreign-born group in the United States (Schulte and Wolf, 1994; Woodrow and Peregay, 1991).

Another source of change that could affect the projected size of the Mexican-origin population is changing rates of intermarriage and/or changing self identification among the children of mixed-ethnicity parents. The projections in Table 6 do not account for the possibility of changes in patterns of exogamy. Intermarriage between racial/ethnic groups may alter the way future generations identify themselves given the present categories of race and ethnicity. Differential patterns of exogamy may alter the projected size of these groups (Bean et al., 1997). Edmonston, Lee and Passel (1994) have presented population projections adjusted for differential exogamy rates among Hispanics and other racial/ethnic groups. Increases in exogamy are built into their projections (see Table 7) and show that the Hispanic-origin population in the United States could vary from between 50.9 million and 77.4 million people by 2040 depending on actual rates of exogamy. Table 7 also presents the projected size of the Mexican-origin population based on the same patterns of exogamy built into the Edmonston, Lee and Passel projections. These projections demonstrate that, if the Mexican population remained approximately

Table 7
Projected Size of the Mexican-origin Population in the United States Adjusted for Potential Exogamy: 1995–2040

	Hispanic-origin Pop'n (in millions)		Mexican-origin Pop'n (in millions)	
	Single Ancestry Only[1]	Single and Mixed Ancestry[2]	Single Ancestry Only[3]	Single and Mixed Ancestry[4]
1990	22.4	22.4	13.4	13.4
2000	28.6	31.9	17.1	19.1
2010	35.0	42.1	21.0	25.2
2020	41.1	53.0	24.6	31.7
2030	46.5	65.0	27.9	38.9
2040	50.9	77.5	30.5	46.4

Notes: [1] Both parents are of Hispanic origin.
[2] At least one parent is of Hispanic origin.
[3] Both parents are of Mexican origin.
[4] At least one parent is of Mexican origin.

60 percent of the total Hispanic-origin population, individuals of Mexican origin would number between 30 and 46 million persons by the year 2040 depending upon actual rates of exogamy.

Estimates of Authorized or Legal Mexican Immigration

Measuring Legal Immigration: Knowns

Administrative Statistics

Admissions for lawful permanent residence, legalization approvals, adjustments to lawful permanent residence, and nonimmigrant arrivals are easily accessible administrative statistics. These would be considered "knowns" in the sense that the data sets are regarded as highly complete within the domain. Interpretive cautions must be noted for using these administrative statistics for social science research. First, those immigrants arriving as permanent residents may have had prior U.S. residence experience or may anticipate short or long stays abroad. Survey responses to questions about the timing of immigration may differ from recorded date of lawful permanent residence. Second, generally-legalized immigrants are usually presumed as having settled here for their lifetimes and at minimal risk of return migration as a consequence of their sustained presence. Third, those adjusting to lawful permanent residence from a nonimmigrant class may have substantial U.S. residence histories, either continuous or on an intermittent basis. Fourth, arriving nonimmigrants are presumed to be temporary residents, and the majority of non-immigrant departures occur following short durations of saty.

Measuring Legal Immigration: Unknowns

The following sub-sections address the major uncertainties stemming from "temporary" migration, emigration after legal immigration, incorporation of the agriculturally-legalized population, and the ultimate immigration consequences of the IRCA legalizations.

Presence of Nonimmigrants

A one-year entry cohort of nonimmigrant arrivals is comprised of (1) aliens who depart and (2) aliens who stay or are lifetime migrants. Among those who depart, most depart within a brief interval and others depart after stays of at least one year. Among those who stay, some adjust to permanent resident status, and others stay as unauthorized or undocumented, but either may have changed among nonimmigrant classes. Those nonimmigrant arrivals followed quickly by departure are not considered as counting toward population change and such individuals

would not meet residence rules for either census enumeration or inclusion in national surveys. Those eventually departing after longer residence periods and those ultimately becoming lawful permanent residents present accounting difficulties. The critical questions is: As of a specific date, how many nonimmigrants have stayed in the United States for at least one year or are likely to do so? The magnitude of the accumulated number of present stayers across various nonimmigrant arrival cohorts is needed to estimate the legally resident foreign-born populations for dates falling within the transition between nonimmigrant status and departure or adjustment to permanent status. Their presence is hidden until their adjustments are recorded in immigrants statistics.

This problem is difficult conceptually, analytically, and empirically. The appropriately detailed arrivals and departures statistics are not yet published for monitoring the nonimmigrant population, although considerable improvements have been made. Departures statistics have not been published regularly and are incomplete because the departure portion of the I-94 form may not be collected at exit or INS may receive it much later. Interpreting the net difference of 3.3 million for 1994 (22.1 million arrivals less 18.8 million departures [U.S. Immigration and Naturalization Service 1996b]) is impossible without modeling nonimmigrant processes of arrival, departure and adjustment over time with modification for undercoverage.

The residence rules for the census stipulate that individuals shoulds be living here on a permanent basis or should have lived here for at least six months. Therefore, even when migration may not be for the purpose of permanent residence, six months of residence might be considered a threshold for considering nonimmigrants as usual residents. The 1980 estimate of Warren and Passel included about 612,000 nonimmigrants whose class of admission was taken to imply "usual" residence—243,000 refugees, 192,000 students, and 177,000 other aliens (Woodrow 1990). Throughout the 1980s, the presumption was that newly-arriving nonimmigrants becoming "usual" residents for several months were offset by departures, including adjustments of status of similarly "usually resident" nonimmigrants. This could be a shaky assumption because the annual number of nonimmigrant arrivals has tripled relative to 1970. A total of 1,150,000 nonimmigrants adjusted to lawful permanent residence during 1990-1994. Thus there are about 230,000 annually who are identified as long-term temporary migrants.

Emigration after Legal Immigration

The volume of authorized or legal immigration rose over the 1960s, 1970s and 1980s. Following the post-war period of low immigration and low emigration, the magnitude of emigration after legal immigration, also known as return migration

or re-migration, also began to shift upward. Absent official counts for departing immigrants, several indirect approaches described possible emigration levels for the 1960s, 1970s, and 1980s decades (Warren and Peck, 1980: Warren and Kraly, 1985; Warren and Passel 1987; Woodrow-Lafield, 1996a; Ahmed and Robinson, 1994, Borjas and Bratsberg, 1996).

The crucial question is whether emigration levels for 1960-1980 are sufficiently descriptive of emigration levels for 1960-1990 and 1960-1999, or whether emigration has perpetually increased in the latter half of the 20th Century as the foreign-born population increased dramatically. Emigration levels might be unchanged because emigration rates may be lower among contemporary immigrant residents than among earlier cohorts. Origin or other characteristics associated with lower propensity to emigrate may be more highly represented among foreign-born residents. Indeed, the compositional mix of the foreign-born population has shifted to include greater proportions of (1) Latin Americans and Asians for whom emigration has seemed lower than for Europeans (Jasso and Rosenzweig, 1990); Warren and Kraly, 1985) and (2) immigrants who entered under visa categories associated with lesser likelihood of return migrating, such as refugees, asylees, adjustees from nonimmigrant statuses, and formerly undocumented or temporarily resident individuals.

The preponderance of evidence about emigration is more adequate for positing a broad range than for stating that emigration levels are higher in the 1980s than in the 1970s. The empirical evidence is mixed. First, several studies support a range for 1980 census coverage research of about 0.9 to 1.9 million foreign-born emigrants. Second, there is variance among estimates of emigration for the 1980s. A newly applied approach in the U.S. context, multiplicity sampling-based surveys of U.S. residents about nonresident relatives, supported a broad range for emigration occurring over 1980-1989 (Woodrow-Lafield 1996a). In combination with sensitivity analyses in Woodrow (1991b) based on using emigration rates by age, sex, period of entry, and country or region of origin, the preliminary evaluation of 1990 census coverage employed an estimate of 1.33 million for net emigration of legally resident foreign-born for the 1980s and allowed for variation between 0.8 million and 2.2 million. A re-application of Warren and Peck's (1980) intercensal approach yielded a result toward the upper end of this range (Ahmed and Robinson 1994). Although this study was taken to support higher emigration in the 1980s than in the 1970s and a higher allowance for population programs, the U.S. Bureau of the Census took an evenhanded approach in also increasing the allowance for net population change due to net undocumented migration.

For the present purposes of positing estimates for net legal immigration as of the 1980s and 1990s, we make assumptions about the level and composition of emigration flows that are generally consistent with prior research for the 1960s

and 1970s. For post-1989 analyses, alternative series will show the effects of varying assumed emigration from 95,000 to 195,000 annually. Legal foreign-born emigrants will be distributed to Mexico as country of origin and to all other countries of origin on the same basis as for undocumented research (Woodrow and Passel 1990; Woodrow 1992c).

The Mexico-born population has increased dramatically since 1950, but that increase has been dominated recently by legal immigration—primarily family-based and legalization-based. In one sense, there might seem to be lesser propensity for return migration given a greater density on legal status, greater demographic diversity, and possibly greater representation of sending communities at migration maturity. Alternatively, the Mexico-born population could ultimately reach a time at which Mexican return migration could emerge as more easily discernible, despite limitations of methodologies, simply because of its volume as a function of the larger size of immigrant cohorts over the 1970s, 1980s, and 1990s. Such a shift could be detectable, if not precisely measurable, by comparing multiplicity sampling-based estimates of Mexican emigrants over time, as Woodrow-Lafield (1996a) found for the post-IRCA period between 1987 and 1988.

The SAWs Population

In referring to the agricultural legalization, meaningful distinctions exist among SAW applicants, SAW-approved beneficiaries, SAW-default beneficiaries, and residents becoming SAW-approved beneficiaries. The SAW beneficiaries may not be presumed automatically as living in the United States because their "proof" of agricultural work experience was insufficient for establishing usual residence in the United States. Migrant agricultural workers have historically commuted for lengthy periods of time as part of the settlement process (Massey 1986; Lowell 1992; Tilly 1990). Because about 700,000 SAW applications were filed in May 1988-November 1988 (498,000 in the last two months), the SAW program may have been a magnet for aliens seeking U.S. residence status and may have ultimately promoted migration to and settlement in the United States (Also, see Martin 1990, 1994, 1996.)

Further confusing the issue of whether SAW beneficiaries live in the United States or their origin country, which was Mexico for 81.6 percent, the INS automatically granted lawful permanent resident status to all SAW beneficiaries. That benefit was extended to both SAW-approved beneficiaries and SAW-default beneficiaries, whose applications INS simply failed to deny, with about 900,000 becoming "lawful permanent residents" by the default deadline of December 1, 1990. Thus, the single action of SAW application yielded entitlement for U.S. permanent residence.

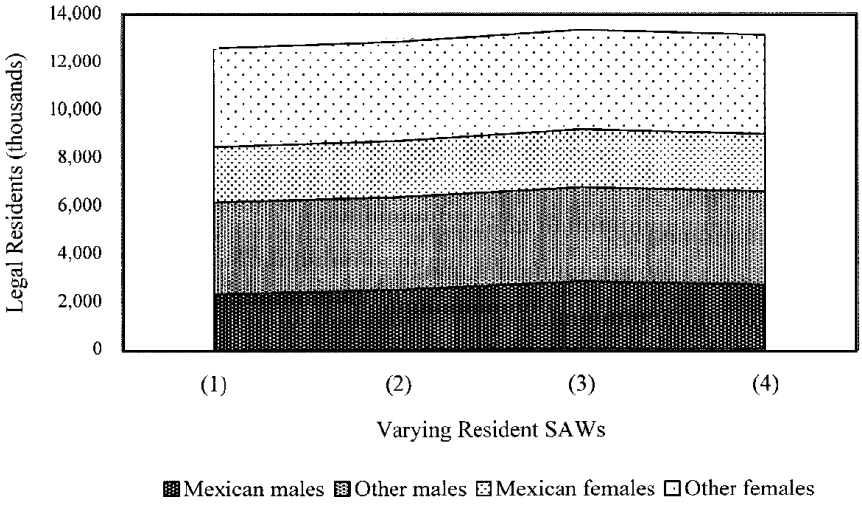

Figure 3. Legally Resident Foreign-born in 1989 by Mexican-born and Resident SAWs

There are limited insights to SAWs' behavior following legalization. The National Agricultural Workers Survey (NAWS) acquired individual migrant workers' legal status; almost one-half of the migrant workforce in 1989—1991 has legalized under IRCA (Gabbard, Mines, and Boccalandro 1994). Samardick (1995) reported that about 32 percent of Mexico-born migrant workers in 1993-1994 had received SAW status and that about 7 percent had generally legalized after long-term undocumented residence. Many of the SAW beneficiaries appear to have continued working in seasonal agricultural services.

Another indicator of SAW beneficiaries' residence in the U.S. rather than their origin country will be their behavior in seeking to naturalize. Naturalization statistics for fiscal year 1996 showed a continued upward trend, but application levels for naturalization among eligible generally-legalized immigrants or SAW beneficiaries are not known. Application rates among the generally-legalized population have been tracked in only a very limited fashion (U.S. Department of Labor (1996:107).

Immigrant Flow Effects from IRCA

The presence of IRCA beneficiaries' family members in the United States must be viewed carefully in building an accounting model for the legally resident foreign-born population. The demographic consequences of the general legalization program under IRCA will be considerable with as many as 2.5 million future immigrants

related to these legalization beneficiaries, including 1.6 million Mexican relatives (Woodrow-Lafield 1994a). Approximately 136,000 spouses, 223,000 children, 30,000 parents, 130,000 siblings, and 102,000 other relatives are estimated as living in the IRCA beneficiary households and having non-resident statuses (family fairness, temporary visa, other, or missing). Within households of legalized Mexican immigrants, there were 91,000 spouses, 159,000 children, 19,000 parents, 99,000 siblings, and 69,000 other relatives in nonpermanent statuses, totaling 436,000 (unpublished analyses by Woodrow-Lafield). In a demographic accounting analysis of the resident population, resident dependents of IRCA beneficiaries will be incorporated in the estimated legally resident foreign-born population in a lagged fashion as they become legal immigrants with the allocated visas for 1992-1994, with second preference (or first, third, or fourth preference) visas in some year, or under provisions for immediate relatives (parents, spouses, or minor children) of U.S. citizens.

IA90 specified that up to 55,000 visas might be granted for spouses and children of legalization beneficiaries to avoid family disruption. This largesse was apparently insufficient because (1) a lesser amount resulted—140,000; (2) the second preference visa waiting list counts associated with legalization beneficiaries were 739,774; 853,382; and 824,000 in fiscal years 1993, 1994 and 1995 (U.S. Department of State 1993, 1994, 1995 U.S. Commission on Immigration Reform 1995). Many (one half million) of these spouses and children are probably related to beneficiaries of the SAW or agricultural legalization (Woodrow-Lafield 1995b). The waiting list under second preference is so clogged that waiting times for new applicants are growing progressively longer.

A more expedient way for these close family members to legally immigrate to the United States will be the two-tier processes of the IRCA beneficiary's naturalization and sponsorship of their spouses and minor children under immediate relatives provisions for which there are no limitations except for those who were minor children at the time of visa petition filing who aged into adulthood and were ineligible for visa issuance. Among Mexican respondents in the 1992 LPS, nearly three-quarters indicated they would either "definitely" or "probably" apply for naturalization upon becoming eligible (Woodrow-Lafield 1995c). This study supported a cost-benefits strategy in naturalization decision-making in that having a co-resident sibling without permanent status and having a parent or sibling intending to immigrate are significantly associated with intending to apply for naturalization. The numbers of spouses and children who could become legal immigrants under immediate relatives' provisions during 1996-1999 could exceed one half million.

Demographic Accounting for Unauthorized or Legal Migration

Legally Resident Foreign-born Population in 1980

Warren and Passel (1983, 1987a, b) first formulated a baseline estimate for the alien component using the Annual Alien Address Registration Program for January 1980 according to self-reported residence status. The 1980 alien data were adjusted for estimated underregistration of 11.1 percent, resulting in an overall increase of 12.5 percent. For Mexico, Warren and Passel estimated that 7.3 percent of legally resident aliens had failed to register (Passel 1991). An estimate of naturalized citizens in the 1980 census was based on both census reporting as naturalized citizens and a demographic estimate constructed by surviving naturalizing immigrants over time, as identified with INS administrative naturalizations statistics. A major criticism directed at this work on the undocumented population was that the authors assumed that INS sources correctly recorded naturalizations over 1960-1980 (Hill 1985b), but classification by citizenship was unnecessary for derivation of an undocumented estimate, and subsequent demographic accounting was for the foreign-born category.

The Warren-Passel estimate for 1980 of 12,084,000 legally resident foreign-born persons, including 7,816,000 aliens and 6,118,000 naturalized citizens was meant to represent the complete population of legally resident foreign-born persons as of January 1980. Included were 2,326,000 persons of Mexican birth, with 2,121,000 aliens and 205,000 naturalized citizens. An obvious weakness is an inconsistency with 1980 census data for foreign-born persons entered before 1960 in that the census counts were lower than Warren and Passel's estimate for all countries or regions other than Mexico. Demographic research on legal status of the foreign-born population has emphasized the "Entered After 1960" population, with inclusion of Mexicans who entered pre-1960.

The nature of the data collection over a one-month period also raises concerns because the population estimate would probably over-represent shorter durations and lead to over-estimating the population entered for the most recent time period. Hill (1985b) raised questions about over-reporting for Mexico, among other countries, possibly as a result of misreporting by temporary residents in the category for permanent resident. Subsequently, Passel (1991) allowed for greater variability in the legally resident alien component for the Mexican population (+10 percent) than for the non-Mexican population (+3 percent), noting that undocumented migrants might have erroneously registered.

The estimate of legally resident foreign-born persons as of 1980 by Warren and Passel can be considered a "standard" in several senses, and it became a foundation for using a components-of-change method to derive post-1980 estimates for legally resident foreign-born populations in the United States. The major

components of change are estimated mortality, assumed emigration, admissions of lawful permanent residents and certain groups of arriving refugees, and other transitions to lawful permanent residence by persons already living in the United States (including adjustments and legalizations). This methodology was designed for consistency with the Census Bureau's methodologies for demographic analysis and postcensal population estimates.

An accounting for components of change for the resident population was equivalent to accounting for components of change in the legally resident population before 1980 because an undocumented presence had not yet been measuraæble. After the 1980 census apportionment counts exceeded the independent estimate, the Census Bureau endeavored to improve estimates of the number of illegal aliens and make public a sufficient number of undercount estimates to illustrate the uncertainties in the methods (ASA Technical Panel, 1984). To this end, a systematic research program at the Census Bureau monitored net legal immigration in the 1980s and indirectly monitored net undocumented migration by partitioning survey estimates for the foreign-born population into legal and undocumented components (Passel and Woodrow 1987; Woodrow, Passel and Warren 1987; Woodrow and Passel, 1990; Woodrow 1992c).

Table 8 summarizes the 1970-1990 time series of estimates of the foreign-born population, legally resident foreign-born estimates, and estimates of unauthorized residents in surveys or censuses. Post-1986 estimates required accounting for IRCA-legalized aliens' transitions from undocumented resident to legal resident. Those legalizing on the basis of having lived here continuously in an undocumented status since before 1982 are *prima facie* permanent residents. The figures in Table 8 incorporate most of the general legalizations, but alternative estimates based on allowing for agricultural legalizations are discussed below.

To the degree that there is undercoverage of either the legally resident or undocumented residents, there will be underestimation of the unauthorized component (Woodrow-Lafield 1995a). Because foreign-born undercoverage is not known, a potpourri of rationales have been discussed for a range on the total number of unauthorized residents over 1980-1990. Despite the passage of time, these ranges are not really very different. The most consensual is the range for 1980 that relies on several studies suggesting that the probable upper bound of the unauthorized population was 3.5 to 4 million (Bean, King, and Passel 1983; Levine, Hill, and Warren 1985; Passel and Robinson 1988; Heer and Passel 1987.

These studies were the foundation for the net unauthorized migration component for evaluating the 1990 census (Woodrow 1991a) which is discussed more later. It must be noted that an estimate for legally resident foreign-born population was implicit rather than explicitly stated and that the net "unauthorized" migration component possibly included agriculturally legalized residents. The last two studies

Table 8
Estimates for Foreign-born, Legally Resident, and Unauthorized Populations
Based on Demographic Accounting: 1970-1990

Date of Estimate	Foreign-born in census or survey			Legally resident foreign-born in U.S.		Estimated unauthorized residents in survey or census	Hypothetical total number or range (in millions)	Relevant Sources
	All Periods	%	Post-1960	All periods	Post-1960			
1970 Census	9,739,723	4.0%	3,316,928	9,739,723	3,316,928	0	0.8	Passel & Robinson (1988)
Nov. 1979	13,198,000	5.8%	8,760,000	11,474,000	7,036,000	1,724,000	none given	Passel & Woodrow (1987)
								Woodrow, Passel, & Warren (1987)
1980 Census	14,139,000	6.2%	9,230,000	12,082,000	7,173,000	2,057,000	2.5 to 3.5;	Warren & Passel (1983, 1987)
								Passel (1985b)
								Passel & Robinson (1988)
							2.0 to 5.0;	Fay, Passel, & Robinson (1988)
							1.5 to 3.5;	Hill (1985)
							2.0 to 4.0	Levine, Hill, & Warren (1985)
April 1983 (14+)	13,633,000	7.4%	9,949,000	11,540,000	7,855,000	2,093,000	none given	Passel & Woodrow (1987)
June 1986	16,237,000	6.8%	13,069,000	13,079,000	9,911,000	3,158,000	3.0 to 5.0	Woodrow, Passel, & Warren (1987)
								Passel & Woodrow (1986)
June 1988	17,185,000	7.0%	14,379,000	15,279,000	12,473,000	1,906,000	none given	Woodrow & Passel (1990)
Nov. 1989	17,785,000	7.3%	15,154,000	15,735,000	13,104,000	2,050,000	1.7 to 3.1	Woodrow (1990, 1991b, 1992b)
Projected April 1990	19,090,000	7.5%	15,754,000	16,690,000	13,354,000	2,400,000	3.3	Woodrow (1991b)
							1.9 to 4.5	
1990 Census	19,768,000	8.0%	16,628,000	17,690,000	14,354,000	2,274,000	2.3 to 5.0	Woodrow-Lafield (1995)
1990 Census	19,724,000	8.0%	none given	17,749,000	none given	1,975,000	none given	Clark et al. (1994)

Note: Most foreign-born population figures include estimated amounts for misreporting as native foreign-born persons.

Source: Woodrow-Lafield, Forthcoming

mentioned in table 8 (Woodrow-Lafield 1995a; Clark et al., 1994) make allowances for nonspecific sources of legal immigration, including agriculturally legalized residents, and we return to these results a closer examination of studies for the 1979-1989 period.

The legally resident Mexico-born population in the United States increased from about 1.4 million in 1980 to 3.0 to 3.5 million for 1990 (Table 9), depending on particular assumptions. The unauthorized population of Mexican birth appears to have fluctuated and to have declined slightly for 1990 relative to 1980, but this appearance may be artifactual due to the survey or census estimate. Prior to IRCA, extrapolation of studies of average population change due to net unauthorized migration from Mexico implied there were as many as 2.5 to 3.5 million unauthorized Mexican residents, but the post-IRCA range was lower—1.0 to 2.2 million (Woodrow -Lafild 1996e). These estimates for legally resident foreign-born populations are only as accurate as they are unbiased from data gaps on emigration or return migration and unknown long-term immigration associated with nonimmigrants or agriculturally legalized persons. Exercising expert judgment is inescapable, but guiding strategies are nonexistent. The number of unauthorized residents in 1990 was certainly below six million (Woodrow-Lafield, 1997).

Without Accounting for IRCA Legalizations

Prior studies showed post-1986 estimates for the legally resident foreign-born population without any amnestied aliens pursuant to IRCA only for the purpose of estimating net population change due to undocumented immigration. Without allowing for legalization pursuant to the amnesty provisions of IRCA, the foreign-born population legally resident would have grown from 7,036,000 to 11,440,000 over 1979-1989 (second tier, Table 9). This increase is only from post-1981 immigration. Recently admitted legal Mexico-born immigrants accounted for slightly more than one-tenth of net legal immigration for the post-1981 entry period.

With Accounting for Generally Legalized Immigrants

The featured or preferred estimates for the legally resident foreign-born population showed an increasing trend over 1979-1989. The rate of increase was greater for the Mexico-born population legally resident as the number more than doubled over that decade from 1,388,000 to 2,522,000. Without considering origin, most of the increase is attributable to post-1981 immigration. With closer examination, most of the increase for the Mexico-born population falls within the pre-1981 entry reference period—almost wholly from the IRCA legalization

Table 9
Estimates of Net Legal Immigration with Legalizations, 1979–1989, Total and Mexican-born

Data and Source	Total (in thousands)			Mexico-born (in thousands)		
	Total	Entered Before 1982	Entered After 1981	Total	Entered Before 1982	Entered After 1981
Preferred

1989, Woodrow (1991a, 1992c)	14,104	8,887	5,217	3,799	2,522	1,277

of aliens proving continuous undocumented residence since before January 1, 1982. As a reminder, these estimates of the legally resident foreign-born population were produced under the auspices of the Census Bureau's 1980 and 1990 census coverage evaluation programs and, accordingly, are intended to represent those individuals meeting the Census Bureau's criteria for living in the United States on a usual basis.

With Incorporation of Agriculturally Legalized Beneficiaries as Residents

Recalling earlier discussions about the SAW legalization program, the issue of SAW applicants' inclusion in the legally resident estimate, national surveys or the census, and in survey-based undocumented estimates were not very important during 1988-1990. For example, the review of the unauthorized immigration component by Himes and Clogg (1992) mentioned only the generally legalized immigrants. Until the deadline of December 1, 1990, the INS might have refused many of the applicants on the basis of having shown insufficient grounds. Making any allowance for agricultural legalization beneficiaries' residence affects primarily the overall foreign-born and Mexico-born legally resident populations.

Shown in the lower four tiers of Table 9 are illustrative estimates based on alternative assumptions about inclusion of SAW applicants as legally resident for November 1989. The scenarios, similar to those presented in Woodrow and Passel (1990) and Woodrow (1992c), are:

- Low assumption of SAW beneficiaries as residents, for which each SAW beneficiary is assumed to have resided in the United States, on average, for three months, implying that 250,000 would be included;

- Moderate assumption of SAW beneficiaries as residents, for which each SAW beneficiary is assumed to have resided in the United States, on average, for six months, implying that 500,000 would be included;
- High assumption of SAW beneficiaries as residents, for which 550,000 SAW beneficiaries (including 100,000 Group I and 450,000 Group II) are assumed as continuously resident in the United States and for which 450,000 SAW beneficiaries are assumed to have resided in the United States, on average, for six months, implying that a total of 775,000 would be included;
- "All" assumption of SAW beneficiaries as residents, for which nearly all SAW beneficiaries are assumed to have resided in the United States permanently, for inclusion of 1,000,000.

The effect of incorporating SAW beneficiaries as residents increases the post-1981 portion of net legal immigration with especially marked increase for the Mexico-born population. In light of the heavily male composition of the SAW applicant pool, the 1988 and 1989 studies also considered composition by sex. Given implications of these legally resident estimates for derivation of undocumented estimates, it appeared in the late 1980s as if the demographic and origin characteristics of the SAW applicant pool constrained the feasible assumptions to the "low" and "moderate" ones. Allowing for inclusion of more than 500,000 SAW applicants (perhaps 425,000 from Mexico) in the legally resident estimate led to unbalanced sex ratios and implausible undocumented estimates based on the 1988 and 1989 CPS (Woodrow and Passel 1990; Woodrow 1991a, 1992c). Some or many SAWs may certainly have been living in the United States prior to final INS processing and simply have been omitted from the CPS estimates of the foreign-born population. The likelihood of high census and CPS undercoverage for SAW beneficiary residents is obvious, particularly if they resemble agricultural migrant workers (Kissam 1993; La Cooperativa Campesina de California 1991). Gabbard, Kissam, and Martin (1993) discussed the travel patterns of migrant workers as explanations for their finding of extremely high census undercoverage for this special population.

Demographic analysis of 1990 census coverage required an estimate of the total resident population, including the undocumented population residing in the United States on April 1, 1990 by May 1991, prior to the Secretary of Commerce's decision on whether to adjust the 1990 census apportionment counts for undercoverage. However, demographers could not replicate previous analyses, that is, compare the legally resident foreign-born population estimate as of Census Day 1990 with the 1990 census count of the foreign-born population which was unknown until early February of 1992 (U.S. Bureau of the Census 1993a. b). For the

demographic analysis program over 1990-1991, the major emphasis was on measuring overall undercoverage of all residents by age, sex, and race with lessor emphasis on legally resident undocumented populations differentiation. In Robinson et al's (1993) analysis of 1990 census coverage, the implicit estimate for legal foreign-born residents as of Census Day 1990 would be 16.7 million as a minimum after incrementing the November 1989 estimate of Woodrow (1991a, 1992c) with 250,000 additional legal immigrants over December 1989-March 1990 as described in Woodrow (1992b) and Woodrow-Lafield (1995a). That figure would have included at least 3 million Mexico-born legal residents. For the "entered since 1960" population, the overall figure would be 13.4 million.

A prime source of uncertainty about the legally resident foreign-born population for 1990 is the size of the resident population having benefited from the agricultural legalization provisions of IRCA. With assumptions about resident SAW beneficiaries, the overall estimate could increase to 17.6 million and the Mexico estimate would increase markedly to 3.8 million. The component for legal immigration over the 1980s was bounded by 5.9 and 8.3 million for modeling uncertainty in the total resident estimate (Robinson et al., 1991, 1993). The two published estimates for legally resident foreign-born persons 1990 shown in Table 8 and for the Mexico-born portion shown in Table 9 are similar in their methodological divergence from pre-1990 census studies. Citing nonspecific sources of legal immigration, including SAW beneficiaries, nonimmigrants becoming permanent residents in the 1990s, special EVD and TPF statuses, and dependents of IRCA-legalized beneficiaries, Woodrow-Lafield (1995a) used estimates of 14.354 million and 17.690 million for the legally resident foreign-born population entered since 1960 and entered in all time periods. Clark et al. (1994) similarly allowed explicit amounts for SAW beneficiaries' presence, foreign students, and other nonimmigrants for estimates of 17.749 million, including 3.469 million Mexicans.

Most of the lawful permanent resident admissions in Fiscal Years 1990 and 1991 were legalization adjustments. In 1990, most of these legalization adjustments were to generally legalized immigrants, and 1991 was the peak year for agricultural legalization adjustments, primarily of the SAW-default approved beneficiaries.

Net Legal Immigration Alternative Series, Varying Emigrants, SAW Beneficiaries as Residents, or Other Nonspecific

Alternative series of estimates for net legal immigration as of 1990 and for 1995 are presented in Table 10 that consider uncertainties as to emigration of legal immigrants, incorporation of SAW beneficiaries as U.S. resident, and nonspecific sources of net legal immigration. The range for the low (95,000), moderate (133,000),

Table 10

Net Legal Immigration, 1990 and 1995, Alternative Series, Varying Assumptions on Specificity, Residence of Agricultural Legalization Beneficiaries, and Emigration

Description and Assumptions	Total Entered 1960-1990	Mexico-born Entered Before 1990	Total Entered 1960-1995	Mexico-born Entered Before 1995
With low-zero allowance for nonspecific,				
Without any allowance for SAW beneficiaries as residents,				
1. With low assumption for emigration (95,000)	14,004	3,307	16,825	3,928
2. With moderate assumption for emigration (133,000)	13,641	3,264	16,281	3,864
3. With extreme assumption for emigration (195,000)	13,092	3,199	15,457	3,766
With low-zero allowance for nonspecific,				
With low allowance for SAW beneficiaries as residents (300,000, 250,000 Mexican),				
4. With low assumption for emigration (95,000)	14,304	3,557	17,125	4,178
5. With moderate assumption for emigration (133,000)	13,941	3,514	16,581	4,114
6. With extreme assumption for emigration (195,000)	13,392	3,449	15,757	4,016
With low-zero allowance for nonspecific,				
With moderate allowance for SAW beneficiaries as residents (550,000, 450,000 Mexican),				
7. With low assumption for emigration (95,000)	14,554	3,757	17,375	4,378
8. With moderate assumption for emigration (133,000)	14,191	3,714	16,831	4,314
9. With extreme assumption for emigration (195,000)	13,642	3,649	16,007	4,216

Note: See text for explanation of various assumptions and other details of these calculations.

and extreme (195,000) assumptions about annual levels of emigration is narrow, although those differences would accumulate over the number of years. For the Mexico-born, these assumed amounts of emigration are slight—9,000, 13,000, or 20,000 in accordance with Warren and Passel (1987b). The range for incorporation of SAW beneficiaries as residents is 300,000 (250,000 for Mexico), 550,000 (400,000 for Mexico), or 850,000 (700,000 for Mexico). The range for nonspecific sources of legal immigration is zero for the low, 700,000 (250,000 for Mexico), or 1,000,000 (800,000 for Mexico). This latter set of assumptions is intended to encompass those individuals whose status might be considered as neither legal nor undocumented at the present time who would become legally resident especially as possible through naturalization of a relative who is an IRCA legalization beneficiary.

The columns for net legal immigration for entry 1960-1990 are based on carrying forward the estimated legally resident foreign-born population of Woodrow (1991a, 1992c) from December 1, 1989 to April 1, 1990 primarily with additional legal admissions and additional general legalizations for most tiers. The columns for net legal immigration for 1960-1995 are constructed by surviving the 1989 base estimate until 1995, adding surviving numbers of admissions of lawful permanent residents 1990-1995 (net of legalization adjustments), subtracting estimated emigrants, and adding generally legalized, agriculturally legalized, and nonspecific components as indicated.

The first tier of estimates (1) through (3) for the legally resident foreign-born population or net legal immigration as of 1990 or 1995 are most consistent with the Census Bureau's procedures for counting individuals as contributing to the resident population as immigrants or settlers. This set is the lowest representation of net legal immigration. The second tier of estimates (4) through (6) is slightly higher to reflect a low allowance for agriculturally legalized residents. With set (5), the estimate is about the same as that of Clark et al. (1994). Among all the estimates, including the other tiers, sets (7) through (30), the amount of net legal immigration as of 1990 ranged between 13,092,000 (3) and 15,854,000 (28). The amount of net legal immigration from Mexico as of 1990 ranged between 3,199,000 (3) and 4,807,000 (28). Figure 4 depicts net legal immigration for 1979-1995 with sets (2) and (17) for all countries and for Mexico. Depending upon which alternative series might be the most accurate, the divergence from prior estimation strategies would be greater or lesser.

Net legal immigration from all countries over 1960-1995 shows an increase of more than 2 million. The low estimate appears in set (3)—15,457,000—and the high estimate in set (28) is 18,675,000. Net legal immigration of Mexicans as of 1995 ranged from 3,766,000 (3) to 5,428,000 (28). The extreme allowance for nonspecific sources of legal immigration may be beyond the range of reality, so that these upper limits might be shifted downward to set (19)- 18,375,000 for all countries and 4,878,000 for Mexico.

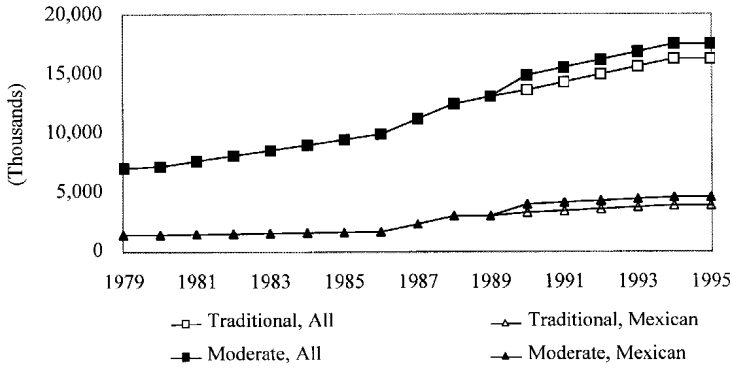

Figure 4. Net Legal Immigration, 1979-1995, Alternative Series

To summarize, the upward trend in legal immigration to the United States and, for Mexico, the focused impact of IRCA's amnesty programs, account for a gradually increasing presence of legally resident immigrants since 1980. The precise magnitude is difficult to pinpoint because the extent of U.S. residence among agriculturally legalized individuals, the volume of transitions from undocumented status into lawful permanent residence among family members of legalized immigrants, and timely accounting of nonimmigrants in the United States are not known. Ways of improving estimation for legally resident foreign-born populations are straightforward in concept, but few of the statistical improvements recommended in Levine, Hill, and Warren (1985) or others recommended have been accomplished. The quantity of legal migration is more conservatively estimated with traditional definitions of permanent migration than with less restricted, but probably truer, inferences from multiple data sources.

Estimates of Undocumented Migration

The purpose of this section is to provide an overview of the best analytical approaches and estimates of the stock and flow of the unauthorized Mexican migrant population from the late 1970s to the present. In describing the prevailing methods used for estimating the unauthorized migrant population, including the unauthorized Mexican migrant population, during the late 1970s, 1980s, and 1990s, we illustrate how the methodology and data used for making estimates of the stock and flow of the unauthorized migrant population in the United States in general and the unauthorized Mexican migrant population in particular have changed over the past two decades. We highlight how these changes have led to improvements and, in some cases, to increased inaccuracy associated with estimates of particular components of the unauthorized population. We do not review every individual

estimate of the unauthorized Mexican migrant population because many studies have already been summarized and evaluated competently in other reviews (Keely, 1977; Briggs, 1984; Corona, 1982; Siegel, et al., 1980; Tuirán, 1984, 1994; Hill, 1985b; Bean, King, and Passel, 1986; Bean, Telles, and Lowell, 1987; Edmonston, Passel, and Bean, 1990; Passel, Bean, and Edmonston, 1990; Durand and Massey, 1992; GAO, 1993; Clark, et al., 1994). Rather, we summarize and assess the conclusions of these reviews and describe individual studies where appropriate.

Concepts and Definitions

An unauthorized migrant is a person who resides in the United States but is not a U.S. citizen or permanent resident alien or authorized visitor. Various terms have been used to describe such persons, including undocumented immigrant, undocumented alien, undocumented migrant, unauthorized immigrant, and unauthorized migrant, each of which has a slightly different meaning and connotation. As noted above, we use the term "unauthorized migrant" because it best applies to the population whose size and growth we here attempt to estimate. Not all unauthorized migrants are undocumented; some arrive in the U.S. with legal documents but later either stay beyond the expiration date of their visa or otherwise fail to comply with the terms of their entry (such as persons who legally cross the border with border crossing cards but do so to work, which violates the terms of the card). Also, not all unauthorized migrants are immigrants; many are temporary migrants who intend to and do in fact return to their countries of origin within reasonably short periods of time.

The types of data available and the methodology used to obtain estimates of the unauthorized migrant population sometimes depend on the route through which unauthorized status was attained. There are several ways to become an unauthorized migrant. These include entering without inspection, using fraudulent documentation, or violating the terms of border crossing cards. All violators of these types end up in a category the Immigration and Naturalization Service (INS) calls entrants without inspection (EWIs). Another way involves entering legally as a nonimmigrant but subsequently violating the terms of the entrance visa or other terms of entry (usually through failing to leave the U.S. by the time the visa expires). These are often called "visa overstayers." Still another way involves entering as a legal resident alien but subsequently violating the terms of entry (e.g., through committing a criminal act or using a fraudulent marriage as a basis for entry). Most studies that attempt to estimate unauthorized migrants separately by type of entry focus on the two largest of these groups, EWIs and visa overstayers.

The data and methodology used to estimate the unauthorized Mexican migrant population also depend on whether the estimate refers to the stock of the population

or the flow of the migratory stream. Stock refers to the size of the population at a particular point in time. Flow refers to the number of *entrances* into (in-flow) and *exits* from (out-flow) the population during a given time period. Most estimates of the volume of the migratory flow have focused on in-flow. In-flow in turn may be subdivided into *gross* in-flow and *net* in-flow. Gross in-flow is the total number of entrances made during a given time period whereas net in-flow is the number of persons entering during a given time period. Because an individual may enter the country as an unauthorized migrant more than once in a single time period, net in-flow is almost by definition smaller than gross in-flow. In contrast to in-flow, relatively little attention has been paid to the size and components of the out-flow of unauthorized migrants. Persons may exit unauthorized status through death, emigration, deportation, or legalization. Out-flow is a critical component because the majority of entrances are offset by exits, as indicated by estimates of net flow. Observers who fail to account for out-flow risk highly exaggerated estimates of the rate of growth of the unauthorized migrant population. More attention has been paid to estimating net flow (in-flow minus out-flow). Net flow has typically been estimated as the change in stock as it is estimated at two or more points in time (Passel and Woodrow, 1987; Woodrow, Passel, and Warren, 1987).

Another conceptualization which is related to the idea of stocks and flows but is analytically distinct is the notion of temporary or permanent migrants, or sojourners and settlers, to use the more sociological distinction (Bean, Vernez, and Keely, 1989; Chavez, 1988). Here the reference is to the duration of stay in the destination country, but especially to the migrant's *intended* duration of stay (Roberts, 1995). Such intentions have consequences because the kinds of immigration and settlement policies that might be invoked in the cases of temporary and permanent migrants are not necessarily the same (e.g., see Passel, 1986). Further complicating the situation is that many temporary migrants undergo a transition to permanent migrant status over time. Although it is important to keep in mind that temporary and permanent migrants have a different sociological and policy significance, at another level it is useful to think of these two kinds of migrants as differing only in their durations of stay. At a given point in time, estimates of the stock of Mexican migrants will include both permanent and temporary migrants, the latter of whom are disproportionately likely to return to Mexico within short periods of time. One of the challenges facing the estimation of stocks and flows of migrants, as we note below, is to develop more complete information on the duration of stay distribution of migrants, especially by sex, age at migration, and mode of entry. If such information were available, it would be relatively straightforward to develop estimates of stocks and flows of migrants. Of course, the sociological differences (and their attendant policy implications) between migrants who intend short or long durations of stay would nonetheless remain significant.

Based on the distinctions of mode-of-entry (EWI vs. overstayer) and intended duration of stay, we may construct a four-fold classification of unauthorized entrants (see Figure 5). The groups represented by the boxes (bottom row) in this classification are important because they have implications for policy. Much of the historical and current debate in the United States about illegal migration derives from differences in perceptions about which of the kinds of flows described by these categories dominates the overall flow of migrants, thus affecting growth in the stock of unauthorized migrants. During the 1970s, for example, many observers confused the concepts of stock and flow, mistaking evidence indicating large numbers of entrances for a sizable stock of migrants. In effect, the error was to assume that permanent EWIs substantially predominated over temporary EWIs, when at that point in time the evidence indicated just the opposite was true. Now immigration analysts debate the relative importance of the EWI versus the overstayer flow, a debate that is not likely to be resolved until we can ascertain the relative size of the temporary versus permanent (or short-term versus long-term) component of *each* flow. Thus, if almost all of the visa overstayers were found to return to their countries of origin within two or three years of having violated the terms of their visas, estimates of the stock of overstayers would consist primarily of temporary migrants, however numerous such persons might be at a given moment in time. This scenario would have different policy implications than one in which visa overstayers were generating large numbers of permanent migrants.

Approaches to the Estimation of Stock

Early efforts (during the 1970s and early 1980s) to determine the size of the total unauthorized migrant population produced results that were highly speculative, ranged widely, and were usually much higher than analytic estimates (Keely, 1977; Siegel, et al., 1980, Tuirán, 1984). Despite methodological difficulties and

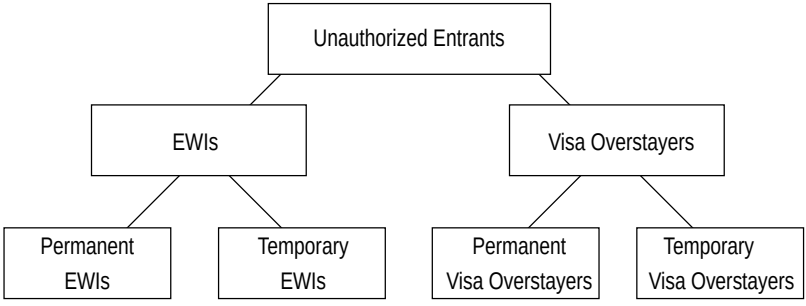

Figure 5. Analytic Typology of Kinds of Unauthorized Entrants Based on Mode of Entry and Intended Duration of Stay

persistently large ranges, more empirically-based and analytic studies produced estimates of stock that failed to support the speculative assertions that there were more than 6 million unauthorized migrants in the country. Some early estimates of the Mexican unauthorized population also relied on Mexican census or survey data as we note below.

Estimates of the size and growth of the unauthorized migrant population in the late 1980s and 1990s attempted to address some of the shortcomings of previous work. During the 1980s, the majority of these new studies employed a residual method of one form or another. Residual methods provide an estimate and description of the "enumerated" unauthorized migrant population, that is, the part of the unauthorized population that is enumerated in the Census or represented in a sample such as the Current Population Survey (CPS) (the unenumerated portion of the population must be estimated by other means, as we discuss below). As noted in the previous section, the enumerated unauthorized population is estimated as the difference between the total foreign-born population enumerated in the Census or the CPS and the legally resident population (total enumerated foreign born - legally resident immigrants = enumerated illegally resident migrants). This computation may be done separately by national origin, period of entry, age, sex, and, depending on the level of detail available in estimates of the legal population, by state and metropolitan area. Hence, a substantial amount of information about the enumerated unauthorized migrant population may be produced by residual methods. Studies that use a residual method are listed in Table 11. Most of these studies were conducted by the Bureau of the Census. Except in the case of Heer (1979) and Warren (1982), residual methods were generally not employed with data collected prior to the 1980s because the 1980 Census was the first decennial census in which a sizable enumerated unauthorized migrant population could be detected through demographic analysis (Fay, Passel, and Robinson, 1988).

Residual estimates of the enumerated unauthorized population are sensitive to estimates of their two components, the total enumerated foreign born and the legally resident foreign-born population (as discussed above). In the series of residual estimates made by Census Bureau researchers, the foreign-born population enumerated in the Census or the CPS is routinely adjusted for errors associated with respondents not reporting country of birth, misreporting citizenship status, and misreporting nativity. The task of approximating the number of legally resident migrants presents greater difficulties. Because respondents are not asked about legal status in the Census or the CPS, estimates of the legal immigrant population must be obtained from external sources. Due to changes in the external data sources available and changes in the legal population brought about by the IRCA amnesty program, different methods have been developed to estimate the size and composition of the legal immigrant population, as noted above.

Table 11
Residual and Other Estimates of the Stock of the Unauthorized Migrant Population in the United States

Author(s), Date of Publication or Release	Estimation Date	Type or Description	Method	Estimate
Heer (1979)	1970 - 1975	Net flow of unauthorized migrants (EWIs) from Mexico	Residual Method 1	82,300 - 232,000 per year; Author's favorite: 116,000 per yr.
Warren (1982)	1979	Unauthorized migrants in 1979 November CPS	Residual Method 1	Total: 1,250,000 Mexican: 734,000
Passel and Woodrow (1984)	1980	Unenumerated unauthorized migrants in the 1980 Census, by state	Residual Method 1	Total: 2,060,000 (CA = 49.8%) Mexican: 1,131,000 (CA = 67.5%)
Warren and Passel (1984)	1980	Unauthorized migrants in 1980 Census	Residual Method 1	931,000 Mexicans
Passel (1985b)	1980	Estimates for SMSAs of unauthorized residents in 1980 Census	Residual Method 1	Sum is consistent with national estimates
Passel and Woodrow (1987)	Nov., 1979 April, 1983	Unauthorized Migrants, total and Mexican, age 14+	Residual Methods 1and 2	1979: 1,273,000 (Mex.: 917,000) 1983: 2,093,000 (Mex.: 1,422,000)
Warren and Passel (1987)	1980	Unauthorized migrants in 1980 Census	Residual Method 1	Total: 2,057,000 Mexican: 1,131,000
Woodrow, Passel and Warren (1987)	June, 1986	Unauthorized migrants in CPS	Residual Method 2	Total: 3,158,000 Mexico: 2,200,000
Woodrow and Passel (1990)	June, 1988	Unauthorized migrants in CPS	Residual Method 3	Total: 1,906,000

Table 11 (Continued)

Author(s), Date of Publication or Release	Estimation Date	Type or Description	Method	Estimate
Woodrow (1991a)	Nov., 1989 April, 1990	Total and enumerated unauthorized migrant populations	Residual Method 3, and various assumptions about undercount	Total: 3.3 million (1.7 to 5.5 million) 1989 CPS: 2.05 million (1.1 to 2.0 million if SAWs included), 1990 Census: 2.4 million (1.8 to 3.2 million)
Woodrow (1992)	1990	Published version of Woodrow (1991a)		
Clark, et. al. (1994)	1990	Unauthorized migrants in the 1990 Census	Residual Method 3 with different assumptions (include half of SAWs in legal population)	1,975,000
Bean, King, and Passel (1983)	1980	Mexican unauthorized migrants	Sex-ratio, age distribution assumptions Data: Mexican Census	1.5 - 3.8 million (no more than 4 million)
Warren (1995)	1990 and Oct., 1992	Total and Mexican-born unauthorized migrants	Constructive Method based on CPS residual estimates, Visa overstayers, and IRCA non-applicants	1990: Total: 2,600,000 Mexican: 1,009,000 Oct., 1992: Total: 3,400,000 Mexican: 1,321,000
INS (1997)	Oct. 1996	Total and Mexican-born unauthorized migrants	Constructive Method based on CPS residual estimates, Visa overstayers, and IRCA non-applicants	Total: 5 million Mexican: 2.7 million

After 1981, the Alien Registration Program was discontinued. As a result, estimates of the legal alien population had to be constructed by projecting forward the 1980 adjusted Alien Registration population to the appropriate year. For each year of projection, numbers of new legal immigrants, refugees and other long-term legal nonimmigrants were added and numbers of emigrants and deaths due to the legally resident foreign born were subtracted. The Census Bureau used this method to estimate the unauthorized population enumerated in the CPS during the 1980s up until the enactment of the IRCA legalization programs in 1988. These studies include analyses of the April 1983 (Passel and Woodrow, 1987) and the June 1986 CPSs (Woodrow, Passel, and Warren, 1987), which were the only CPS data collected before 1988 that included information about nativity. These studies conclude that by June 1986, about 3.158 million unauthorized migrants, 2.196 million of whom were born in Mexico, were detected by the CPS. More importantly, by this time the Census Bureau had compiled consistent estimates of the unauthorized population enumerated in the CPS from 1979 to 1986. Assuming that the rate of undercoverage was consistent across the CPS samples, reliable estimates of net growth of the unauthorized population could be made. The studies indicate that the unauthorized migrant population grew during the early 1980s by about 218,000 per year, and the Mexican-origin unauthorized population by about 115,000 per year. Due to uncertainties associated with assumptions about emigration and disproportionate undercoverage, however, the authors conceded that the annual net growth of the unauthorized population could have been in the range of 100,000 to 300,000, with about half of the growth due to growth in the Mexican-origin unauthorized population.

Most of the error associated with estimates that use this method is due to uncertainties associated with emigration rather than immigration or mortality. The INS keeps accurate records of the number and types of legal immigrants. Also, the component due to mortality is small in comparison to the other two components of change, so the proportion of total error due to error in the number of deaths is small (Himes and Clogg, 1992). However, the INS has not collected data about emigrants since 1957. During the 1980s, the Census Bureau routinely used a mid-range estimate of 133,000 foreign-born emigrants per year. This approximation was based on the results of research pertaining to the 1960s (Warren and Peck, 1980) and the 1970s (Warren and Passel, 1987). During the 1980s, attempts were made to update estimates of the emigration component by analyzing special items included in the CPS during the late 1980s that asked respondents about relatives who emigrated (Woodrow-Lafield, 1996). Although the results of this work do not contradict the estimate of 133,000, it also indicates that other estimates of the annual number of emigrants ranging from about 110,000 to 200,000 would be plausible. To the extent that the actual annual number of emigrants during the 1980s

were consistently higher than 133,000, the legal migrant population would have been overstated and the enumerated unauthorized migrant population would have been set too low. The opposite would be the case if the actual annual number of emigrants had consistently been lower than 133,000. Because annual estimates of emigration are subtracted from the legal alien population for each year the population is carried forward, the error associated with emigration increases with each additional year. In other words, the longer the time data sources on the legal migrant population or emigration are not available, the greater the uncertainty associated with residual estimates.

Another source of error in estimates produced by the method relates to assumptions about undercoverage of the legal immigrant population. The method assumes that all the legal noncitizens are enumerated. In addition, the method assumes that all immigrants who arrived since 1980—regardless of citizenship status—are represented in the CPS. The bias associated with this additional assumption most likely increases over time as the proportion of the immigrant population who arrived after 1980 grows. The error due to this bias is increased even more for the above cited studies because they analyzed CPS rather than census data and the CPS has higher levels of undercoverage than the census (Woodrow, 1991). That is, residual estimates of the enumerated unauthorized population are understated the most when undercount rates of the legal population are the highest. Of course, if the error associated with emigration leads to an overestimate of the unauthorized population, then part or all of the underestimation due to assumptions about undercount of the legal population may be canceled out.

Starting in 1987, about 1.7 million long-term unauthorized migrants and an additional 1.3 million unauthorized special agricultural workers (SAWs) applied for legalization under the amnesty provisions of the 1986 Immigration Reform and Control Act (IRCA). As a result, post-1987 residual estimates of the unauthorized migrant population have to be adjusted to account for this increase in the legal population. In this variation of the residual method, the legal population is constructed in the same way as in the one above, only the number of IRCA legalized migrants are added to the estimate of the legally resident foreign-born population. Studies using this method include analyses of the June 1988 (Woodrow and Passel, 1990) and the November 1989 CPS files (Woodrow, 1990, 1991, 1992), and the 1990 Census (Woodrow, 1991; GAO, 1993; Clark, et al., 1994). The results of these studies show that about 2.3 million (ranging from 1.8 to 3.2 million) unauthorized migrants were enumerated in the 1990 Census, of whom no more than 80 percent were born in Mexico. This research also indicates that had IRCA not taken effect, the unauthorized population would have grown by roughly 200,000 annually between 1986 and 1990, reaching a size 70 percent larger in 1990 than was observed. Most of this difference was due to the large numbers of Mexicans who

legalized under IRCA; Mexicans comprised more than 70 percent of the IRCA legalized population (Woodrow and Passel, 1990).

Estimates produced by this approach may be inaccurate because it is unclear what fraction of the SAW legalized population remained resident in the United States after legalization. Many SAW applicants presumably were seasonal migrant workers who spent a portion of each year in Mexico. Whether to include the SAW population in estimates of the legally resident population is important because each addition to the legal population results in a one-to-one decrease in the estimated unauthorized population. Even though researchers tend to focus on the number of SAWs who were resident in the United States at the time of the Census, it is more important to focus on the number of SAWs who were actually enumerated in the Census. The Census Bureau assumes that an insignificant number of SAWs were enumerated in the Census or CPS. Hence, they do not include the 1.3 million SAWs in estimates of the enumerated legally resident alien population (although they do provide ranges of estimates that result from varying assumptions about coverage of the SAW population).

Clark, et al. (1994) attempt to make estimates based on more plausible assumptions. They assume that in the SAW legalized population all pre-1984 entrants, all non-Mexicans, and about half of the remaining post-1984 entrants were resident in the United States at the time of the 1990 Census. This amounts to 728,000 or about half of the SAW population. Clark, et al. (1994) include all 728,000 in estimates of the legally resident population, resulting in an estimate of only 1.975 million enumerated illegals in 1990 (in comparison, the Census Bureau made a "preferred" estimate of 2.390 million). Although it does seem implausible that no SAWs were resident nor enumerated in 1990, the Clark, et al. estimate of 728,000 could be too high. Even if half of the SAW population were *resident* in the United States in 1990, it is doubtful that more that 40 to 50 percent of this group were *enumerated*. Migrant agricultural workers have the highest rates of undercount among all groups, reaching 60 to 70 percent (Gabbard, Kissam, and Martin, 1993). There is evidence that a large number of SAW applicants were not really farm workers, plus there is no guarantee that farm workers in 1988 continued to be farm workers in 1990. Hence, more SAWs may have been resident in the United States in 1990 than many analysts have thought, and since many of the SAWs may have been working outside agriculture, they may have had higher coverage rates than has previously been assumed.

In sum, residual methods provide reliable, consistent estimates of the size and growth as well as detailed descriptions of the resident unauthorized migrant population. In comparison with earlier analytic studies, the studies that used residual methods during the 1980s and early 1990s were more successful at describing, quantifying, and reducing the range of error associated with their estimates.

Unfortunately, the range of error is likely to grow over time as information about emigration and the size and geographical residence of the legal immigrant population become increasingly out-of-date, and as other changes occur in the legal population, such as those brought about by IRCA. Unless other methods for obtaining accurate information about emigration or the legal immigrant population are developed, residual methods will probably dominate the literature to a lesser extent in the future than they did during 1980s. Another important limitation of residual estimates is that they describe a selective part of the unauthorized population, namely the portion that is probably least mobile and most permanently established. As we describe below, other methods must be used to estimate the total and unenumerated portions of the stock of the unauthorized migrant population.

Approaches to the Estimation of Flows

In comparison of estimates to stock, few speculative estimates have been made about the rate of growth of the unauthorized population. Chapman (1976) guessed that the population grew by 500,000 per year, and Reubens (1980) estimated an annual growth of 600,000 during the 1970s. Despite empirically based analytical evidence that the annual growth of the unauthorized population was considerably less than the speculative estimate of 500,000, the media and others continued to cite the number. As Passel (1985a:6) chided, "The figure of 500,000 per year is widely used even though there is no strong empirical support for selecting this figure over any other. It seems to be popular because it is a nice 'round' figure that is easy for the public to accept."

Analytic estimates of the volume of in-flow and net flow of the unauthorized population tended to refer to different parts of the unauthorized population and ranged widely. These studies are listed in Table 12. Garcia y Griego (1980), using Mexican survey data on migration histories, estimated that the annual in-flow of unauthorized migrants to the United States from Mexico in 1975 ranged from 75,000 to 284,000. Others used INS apprehensions data as a proxy for general patterns in the level of flow of EWIs from Mexico (e.g., North, 1975; Frisbie, 1975). The difficulties associated with using apprehensions data as a proxy for the flow of EWIs are that (1) apprehensions data do not include those who succeed in evading detection, and (2) apprehensions data count arrests, not individuals; arrest data are potentially misleading because they include multiple arrests of the same person. The INS (1976) attempted to estimate the component of fraudulent successful entries by conducting field studies at 15 Mexican border entry points and 10 major international airports. Two teams of immigration inspectors were stationed at each entry point and carried out careful inspections of entrants for fraudulent documents and intent to violate visa terms. Based on this work the INS concluded that

Table 12

Analytic Estimates of the Flows of the Unauthorized Migrant Population to the United States

Author(s), Date of Publication or Release	Estimation Date	Type or Description	Method	Estimate
North (1975)	1960s-1970s	Flow of unauthorized migrants	Apprehensions	Rise in flow during the 1960s, but not in the 1970s.
Chapman (1976)	1974-1976	Non-immigrant Visa-overstays	Matched Visa entrance and departure records of non-immigrants	740,000 failed to leave on time since 1974; over 1,000,000 from before 1974.
U.S. Department of Justice, INS (1976)	1975	Unauthorized migrants entering with fraudulent documents or intents to violate Visa terms	Thorough INS inspections at border points and at 10 major airports, Sept. 1975-Feb. 1976	500,000 successful fraudulent entries
Heer (1979)	1970-1975	Net flow of unauthorized migrants (EWIs) from Mexico	Residual Method 1, CPS data	82,300-232,000 per year; Author's favorite: 116,000 per yr.
CENIET-Garcia y Griego (1980)	1978	Unauthorized Mexican migrant workers	INS apprehensions; migration histories of 822 Mexican males, 1973, prior to entry	Net inflow 1975-1976: 75,000-284,000 problems
Passel and Woodrow (1987)	April, 1980-April, 1983	Annual net flow of unauthorized migrants, age 14+	Residual Methods 1 and 2	100,000 to 300,000 per year
Woodrow, Passel and Warren (1987)	1979-1986 and 1980-1986	Net flow of unauthorized migrants	Residual Methods 1 and 2	1980-86: Total 176,000 per year Mexican 170,000 per year 1979-86: Total 218,000 per year Mexican 115,000 per year

Table 12 (Continued)

Author(s), Date of Publication or Release	Estimation Date	Type or Description	Method	Estimate
Bean, Espenshade, White, and Dymowski (1990)	Nov., 1986-Sept., 1989	Net flow of EWIs (Southern border)	Data: INS apprehensions, controlled for population in Mexico at risk of migration (age 15-34), number of SAWs, and wage and employment ratios	Apprehensions have seasonal pattern, have dropped post-IRCA, and have increased among women and children
Espenshade (1990)	Nov., 1986-Sept., 1988	Gross flow of unauthorized Mexican EWIs (Southern border)	Repeated trials model	Per month: 175,000 unauthorized entries Total: 4,000,000 from 1986-1988
Warren (1990)	1985-1988	Non-immigrant Visa-overstays by country of origin	INS matched arrival and departure records	Annual number: 217,000 to 255,000 (fluctuated by year). Primary country of origin is Mexico
Espenshade (1995a)	1977-1988	Gross flow of EWIs (Southern border)	Repeated trials model	Correlation between apprehensions and flow = 0.9; Flow = 2.2 * apps.

there were 500,000 fraudulent entries into the United States in 1975, although these estimates have been severely criticized because of small sample sizes and variable rates of detection depending on the day of the week, the immigration inspector, and point of entry (Keely, 1977).

Chapman (1976) attempted to measure the visa overstay component of the in-flow of unauthorized migrants by matching INS records of nonimmigrant visa entries and departures. He estimated that from 1974 to 1976, 740,000 nonimmigrants (about 250,000 annually) failed to leave the United States on time. These estimates were almost certainly too high because they included nonimmigrants who left the country but whose departure forms were never filed, were lost, or otherwise never successfully matched with an arrival form. The size of this error was probably large. At the time, the INS collected about 6 million entrance forms from nonimmigrants per year, and departure forms were linked with arrival forms by matching the name of the nonimmigrant (Siegel, et al., 1980).

Summed together, the estimates of in-flow of EWIs and visa overstayers easily matched and even exceeded the speculative estimate that the unauthorized population grew at a rate of 500,000 per year. However, analytic estimates of net flow showed that the out-flow component of the unauthorized migrant migration stream offset much of the in-flow component. Based on an analysis of CPS data, Heer (1979) estimated that the unauthorized Mexican population grew by about 116,000 annually from 1970 to 1975. Although Siegel, et al. (1980) criticized the estimate because of its large sampling error, they concluded on the basis of the study and other evidence that much of the unauthorized migration to the United States appeared to be circular and was offset by return migration to Mexico.

Studies of flow published during the 1990s have exploited the availability of new data and new estimation techniques. The INS has long matched arrivals with departures, terming arrivals that do not match with departures apparent overstays. The latest research using this data goes one step further by attempting to eliminate system error in the data (Warren, 1990). System error refers to false overstays. INS data for 12 countries which are assumed to have no overstays are used to determine the extent of system error (Belgium, Netherlands Antilles, Norway, Sweden, Kuwait, Saudi Arabia, Switzerland, Australia, New Zealand, Surinam, Singapore and Finland). System error is computed separately by class of admission. First, overstays are estimated for each country using the Nonimmigrant Information System (NIIS). Next, system error is subtracted from the rate of apparent overstay. The remainder is multiplied by the number of expected departures to equal the estimated number of overstays. For estimation by state of destination and age, a calculation was made for each category by state or age. The rate of system error was adjusted to match those of the countries.

Nonimmigrant arrivals increased from 9.4 million in 1985 to about 14.3 million in 1988. The annual number of overstays has fluctuated around 217,000-255,000 (increasing 12% in 1986 and dropping 7% in 1987 (following IRCA) and increasing 13% in 1988). The level of system error has dropped continually (10.3% in 1985 to 8.1% in 1988). North America has been the primary region of origin for overstayers (with the most growth occurring among those from Mexico). The top five countries of origin (Mexico, Haiti, the Philippines, Poland and India) were also among the leading countries for application for legal residence under IRCA. Looking at the geographic distribution of those overstaying their visa time limits, those states with the largest foreign-born population also attracted the most overstays. Finally, Warren finds that most overstays were between ages 15 and 44.

Two primary assumptions are associated with this estimation procedure: (1) that there are few actual overstays from the 12 benchmark countries selected so all apparent overstays from these countries are assumed to represent system error and (2) that a single point estimate of system error applies to every country within a category of admission. In addition, the estimates exclude immigrant students who overstay and all those who enter the United States without inspection (EWIs). In a modification of the procedure undertaken as a result of a GAO (1995) scrutiny of the approach, system error was re-estimated on a airline-by-airline instead of country basis. While the revision resulted in somewhat higher or lower figures for a few countries, the overall result was nearly identical to the figures obtained using the previous method.

Apprehensions data have also continued to be used as a way of roughly gauging undocumented migration flows (Jenkins, 1977; Fogel, 1982; Davila, 1986 and Borjas, Freeman and Lang, 1987). Studies focusing on INS apprehensions data published during the 1990s (Bean, et al., 1990; Espenshade, 1990; 1995a; Crane, et al., 1990; Massey and Singer, 1995) have improved considerably over earlier efforts by better controlling for the influence of contaminating variables. Some of these studies also convert apprehensions into border crossings by assessing the probability of getting caught and the population at risk of getting caught, thereby adjusting for multiple apprehensions of the same person in the data (Passel, Bean and Edmonston, 1990; Espenshade, 1995a). In order to gauge the influence of factors that affect flows across the border, these estimates rely on models with sets of demographic, economic, and behavioral variables (the size of young adult population in Mexico (15-34); the number of legalized SAWs; relative wage and unemployment ratios; dummy variables for months to capture seasonality; the number of officer hours and other measures of enforcement on the border for apprehensions) (Bean, et al., 1990).

Apprehensions data are limited because many unauthorized migrants are never apprehended, others may be apprehended many times, and the volume of

apprehensions depends on the amount of effort expended by the INS to apprehend border crossers. Researchers compensate by using some measure of the amount of border patrol effort (Bean, et al., 1990; Jenkins, 1977; Fogel, 1982; and Borjas, et al., 1987) and include measures of the population at risk for apprehension (Bean, et al., 1990). Espenshade (1990, 1995a) takes the analysis one step further by using a repeated trials model that "captures the phenomenon that, once arrested by the U.S. Border Patrol and taken back across the Mexican border, most undocumented migrants are likely to keep trying to enter the United States until they succeed" (Espenshade, 1990:175). Making use of INS data on the number of repeaters to estimate the probability of apprehension, and then using this to convert the number of apprehensions to estimates of the numbers of crossers. Espenshade constructs a time series on the monthly flow of undocumented migrants. He arrives at an estimate for the period January 1977 to September 1988 of about 175,000 per month, or a total inflow of 20.6 million undocumented migrants (that is, *gross* flow of 20.6 million). In another repeated trials study, Massey and Singer (1995) utilize INS apprehensions data combined with data from surveys of migrants, which enable them to estimate return migration. They arrive at an estimate of *net* flow for the period 1965 to 1989 of 5.2 million (or an average of about 18,000 per month, *net*).

Further Issues Affecting Estimates of Stock and Flow

The aforementioned results on the large differences in measurements of gross and net flows underscore the importance of data on return migration to Mexico for stock and flow estimates, including information on the length of time migrants stay in the United States. This is a critical area where more research is needed. Another area needing research involves the question of the degree of underenumeration of the unauthorized population. In what follows in the rest of this section, we discuss these issues and present new evidence on both patterns of return migration and underenumeration.

Return Migration and Duration of Stay Issues

The distribution of the length of duration of stay in the United States among unauthorized migrants by mode of entry and the change in this distribution over time are crucial factors in understanding the significance of various estimates of the size of the unauthorized migrant population. If almost all EWIs were circular migrants staying only a short time, and if almost all visa overstayers returned to their countries of origin within a couple of years or so, the policy significance of unauthorized migration would be greatly different than if either EWIs or visa

overstayers, or both, contained substantial fractions of long-duration migrants. Similarly, long-duration migrants (say those who stay 10 to 20 years or more) but who then return to their countries of origin are different yet again in their implications for policy from migrants who stay permanently.

At present, very little is known about the distribution of duration of stay of EWIs and visa overstayers (although data on this variable are now available for the sub-group of EWIs who have returned to Mexico from the studies conducted by Massey and his colleagues) (e.g., Massey and Espinosa, 1997; Lindstron, 1996). Also, information on the duration of stay of visa overstayers has reportedly been calculated but not released by the INS. One of the reasons duration information is important is because migrants with different durations of stay exert different demands on public benefits. At the extremes, if the periodic flow of EWIs and visa overstayers were each very large, the cumulative stock of unauthorized migrants in the United States at any one point in time could be very sizable sizable even if all durations of stay were relatively short (i.e., even if all migrants were temporary). If EWIs were to exhibit typically longer durations than visa overstayers, they would contribute more to the stock of unauthorized migrants on that count alone.

What does the available evidence suggest about the comparative distributions of duration of stay among EWIs and visa overstayers? In the case of EWIs, almost all of whom are from Mexico, several pieces of evidence point to increasing durations of stay over the past 15 to 20 years: (1) increasing proportions of entire families, including women and children in the Mexican flow (Bean, et al., 1990; Woodrow and Passel, 1990; Cornelius, 1992); (2) possibly decreasing rates of underenumeration of the undocumented Mexican-born population in official U.S. Censuses and surveys, as noted below, a trend that could result from increasing proportions of migrants with longer durations of stay, especially given that census undercount rates in general have not been declining over the same period (Robinson, et al., 1993); and (3) ethnographic studies whose results indicate that Mexican migrants now embarking for the United States show longer intended durations of stay than prior migrants (Cornelius, 1992). Unless a comparable shift has occurred in the duration distribution among overstayers, this would have the effect of raising the proportion of the illegal stock attributable to EWIs. In the case of visa overstayers, the only relevant evidence to our knowledge is Warren's (1995) finding that when overstayers were traced for a year or two longer than the one year that is typically examined for purposes of defining an overstay, about 46 percent had either converted their status or returned to their country of origin. This suggests that if they were followed a bit longer, the vast majority might be found to have converted their status or returned.

Even though durations of stay may be increasing among EWIs, many may still eventually return to Mexico (a pattern we might term long-term circular migration),

particularly in response to life course and economic opportunity factors. Evidence of such a pattern would also have significant policy implications. Tables 13 to 15 present information on the extent of cohort succession among Mexican-born persons based on results from the 1970, 1980, and 1990 U.S. Censuses and the 1994/95 CPSs. Does the evidence in these tables indicate that Mexican migrants tend to return to Mexico after having spent time in the United States, a phenomenon we would expect to be more likely among the undocumented? Because there were hardly any undocumented migrants enumerated in the 1970 Census, we would not anticipate evidence of cohort attrition beyond what we would expect based on mortality in the 1980 data, and this is in fact what we observe. In the cases of 1990 and 1994/95 data, however, evidence of cohort attrition emerges among migrants who have reached age 45 at the end of the period. Since there is no known reason to think this occurs because of migration to some other country, it is reasonable to think it stems from return migrations to Mexico. This phenomenon, of course, would reduce the stock of Mexican EWIs compared to the case where long-term circular migration did not occur and most migrants were permanent.

Underenumeration Issues

Because residual techniques generate estimates of the *enumerated* portion of the unauthorized Mexican population, such approaches underestimate the true size of this population at any given point in time by an amount equal to the size of the *unenumerated* portion of the population. In order to develop estimates of the total size and growth of the unauthorized Mexican population, it is thus important that methods be developed for assessing the size and growth of the *unenumerated* portion of the population. A number of different researchers have made and continue to make assumptions about the underenumeration rate in the unauthorized migrant population that are not substantially empirically-based. For instance, some have argued that the undercount rate for illegals must be at least as high as the highest rate among native-born groups. On the basis of this logic, some analysts argue that undercoverage must be as high as 20 percent, the rate exhibited by native-born African-American males aged 20-29 (e.g., Passel, Siegel, and Robinson, 1982). Others have argued that the undercount rate in the 1990 Census may be at least as high as it was in the 1980 Census (Woodrow, 1991). However, if the unauthorized migrant population were more settled and less concentrated in agricultural occupations in 1990 than in 1980, then the undercount rate in 1990 might be lower than it was in 1980.

Evidence about the size of the unenumerated portion of the unauthorized population for the census years 1980 and 1990 has been obtained by employing one of two different approaches. The first involves direct attempts to estimate first the

Table 13
Components of Change from 1970 to 1980 in the Mexican-born Population Due to Immigration, Mortality, and Other Causes

undercount rate through comparisons of U.S. Census results with external data about small or localized populations, such as school enrollment records, in-depth survey results, and the findings from ethnographic field research. Estimates of the rate of undercount are then applied to the estimates of the size of the unauthorized population enumerated in the Census in order to approximate the size of the entire unauthorized population. The second approach entails first making independent assessments of the entire unauthorized migrant population or national origin groups within the population based on data sources and methods that are thought to be less sensitive to undercount, and then comparing these estimates with the enumerated population in order to estimate the rate of undercount. The results of both of these approaches are reviewed below, first with respect to the 1980 Census enumeration and then the 1990 Census enumeration.

Direct examinations of the level of undercount indicate that between 20 and 50 percent of the stock of unauthorized residents appeared to be missing from the 1980 Census enumeration. One study compared Los Angeles public school enrollments with estimates of families with school-aged children in the 1980 Census (Muller and Espenshade, 1985) (see Table 16). The results indicated that nearly all families in Los Angeles were enumerated, including families of unauthorized migrants. These results are consistent with the observation that the census is better at enumerating settled populations such as unauthorized migrant families than single migrants. The results of the study also suggested that the undercount rate of the entire unauthorized population was probably no greater than 50 percent. This view was substantiated by the results of a survey of Mexican adults living in Los Angeles County (Heer and Passel, 1985, 1987). Foreign-born respondents were asked whether they were legal residents and if so, to show the interviewer their "Green Card" or equivalent evidence of legal status. Foreign-born respondents who indicated they were undocumented or failed to show evidence of legal status were enumerated as unauthorized migrants. Comparisons of the results of the survey with the number of unauthorized Mexican migrants enumerated in the 1980 Census (Passel, 1985b) suggested that the undercount rate among Mexican unauthorized migrants was probably no greater than about 44 percent (Passel, 1985a; Passel and Robinson, 1988) (See Table 17).

Indirect evidence of undercoverage suggests a narrower range of undercount for the unauthorized population, falling roughly between 30 and 40 percent. As noted above, Bean, King, and Passel (1983) attempted to estimate the number of Mexicans who had emigrated to the United States by analyzing the age and sex composition of the population enumerated in the 1980 Mexican Census. Due to uncertainties about the patterns of undercount in the Mexican Census and the age-sex composition of the emigrant population, Bean, et al. (1983) concluded that the number of unauthorized Mexicans living in the United States could be as

Table 16
Studies with Implications for Underenumeration

na: estimate not available.
[a]Implied population based on estimate of undercount (see note below).
[b]Implied undercount rate based on estimate of population (see note below).

Note: The implied population and undercount rates are based on the assumption that 2.1 million unauthorized migrants (1.1 million unauthorized Mexicans) were enumerated in the 1980 Census, and that 2.4 million (1.9 million Mexicans) were enumerated in the 1990 Census.

low as 1.5 million and as high as 3.8 million. Comparing this range with the number enumerated in the 1980 U.S. Census—1.131 million (Warren and Passel, 1987)—the Bean, et al. (1983) estimate implies an undercount between 25 and 70 percent. However, residual estimates of the Mexican unauthorized population enabled researchers to narrow the range of assumptions used in this analysis (Bean, King, and Passel, 1986; Passel, 1985a; Passel and Robinson, 1988). The results of these revisions indicated that there were probably as few as 1.5 million to 1.9 million unauthorized Mexicans migrants in 1980. Assuming that Mexicans comprise about

60 percent of the unauthorized population, this suggests that between 2.5 and 3.2 million unauthorized migrants were living in the U.S. in 1980. A comparison of these estimates with the approximation of the enumerated unauthorized population suggests an undercount rate of 25 to 40 percent among Mexicans and 18 to 36 percent among all unauthorized migrants.

Using a different approach, Borjas, Freeman, and Lang (1991) analyzed vital statistics data to determine the number of unauthorized immigrants missed in the 1980 Census. The method they used is similar to that used by Robinson (1980), except that it yields more precise results because it employs data on the number of deaths to Mexican-born persons residing in the United States (such data became available in 1984 when vital statistics began to record place of birth on death certificates). The methodology used by Borjas, Freeman, and Lang rests on the assumption that (1) all deaths to illegally and legally resident Mexican-born persons that take place in the United States are recorded in the U.S. vital statistics and (2), that the Mexican-born population experiences age specific death rates that are quite similar to those experienced by the U.S. native-born population. If these assumptions hold, then the total Mexican-born population living in the United States may be approximated by dividing the number of deaths to Mexican-born persons by the death rate. By comparing this estimate with the number of Mexican-born persons enumerated in the 1980 Census, the number of unenumerated Mexican-born persons can then be estimated. Borjas, Freeman, and Lang's results indicate that the number of unenumerated unauthorized Mexicans in 1990 was about 800,000. They add this to Warren and Passel's estimate to yield a total of 1.9 million unauthorized migrants from Mexico, which implies a 40 percent undercount rate. The results of this method tend to be highly sensitive to the underlying assumptions. Nevertheless, if the effects of its limitations could be minimized, the method has potential because it is empirically based, it can provide national level results, and it can be used to obtain annual estimates of the unauthorized population by age, sex, and country-of-origin, as we demonstrate below in an application to the 1990 Census enumeration of unauthorized Mexican-born male and female migrants.

To summarize, the results of undercount studies as well as comparisons of external estimates with estimates of the enumerated unauthorized population suggest that at least 60 percent of unauthorized residents were enumerated in the 1980 Census. This implies that there were at most about 3.4 million unauthorized migrants and 1.9 million unauthorized Mexican migrants living in the United States in 1980.

In the case of the 1990 Census enumeration, both direct and indirect evidence suggest that the undercount rate for the unauthorized migrant population was lower than it was in 1980. The direct evidence comes from a series of ethnographic studies conducted by researchers working with the Census Bureau. The main purpose for

conducting these studies was to gain qualitative information about the causes of undercount, although the results of the research can also be used to shed light on undercoverage rates among various populations. The ethnographic evaluations were conducted in 29 different neighborhoods across the United States and Puerto Rico, each of which contained about 100 households. These 29 neighborhoods were selected because they were thought to contain large concentrations of difficult-to-enumerate populations. Experienced ethnographers made an effort to become familiar with the households and household members who lived within the sample area by accessing informal networks and gaining information about the actual residences of people. Their assessments of the numbers of residents were compared with the official Census counts for the sample areas. The results of the comparisons showed that, among those living in areas containing large concentrations of unauthorized migrants, the undercount rate was *at most* 25 to 30 percent. One area, Long Island, had an undercount rate as high as 72 percent, but this result was not typical. The other areas showed undercount rates as low as or lower than 28 percent, and five areas had undercount rates less than 18 percent (GAO, 1993; de la Puenta, 1993).

Indirect evidence of the undercoverage of the unauthorized population in 1990 comes from only a few studies. Although Warren (1995) produces estimates of the entire unauthorized population in 1990, his estimates appear too low and cannot be relied upon. For instance, he puts the total Mexican-born unauthorized population at 1 million, which is 92 percent *lower* than the residual estimate for 1990 (GAO, 1993). Woodrow (1991) makes a "point estimate" of the illegally resident population in 1990 of about 3.3 million (assuming a 25 percentage undercount). Woodrow (1991) constructs this estimate by projecting forward the estimated 1980 illegally resident population to 1990, adjusting for net growth during the 1980s and legalizations due to the amnesty provisions of IRCA.

Another study showing indirect evidence of the undercount rate in 1990 was conducted by GAO (1993) in consultation with Corona Vasquez (1991). By comparing the Mexican population enumerated in the Mexican Census in 1980 with those enumerated in the 1990 Mexican Census, Corona Vasquez (1991) estimated that 1.5 to 3 million Mexicans emigrated during the decade. By adjusting this estimate for differential undercount and legal migration to the United States, GAO (1993) concluded that about that about 2.7 million unauthorized Mexicans were present in the United States in 1990. Assuming that Mexicans comprise about 80 percent of the total unauthorized migrant population (based on the 1989 CPS residual estimates), GAO puts the total unauthorized migrant population at 3.4 million. Like the results obtained from the ethnographic studies, these two estimates imply an undercount rate of about 30 percent. This level of undercoverage implies an unauthorized population of about 3.4 million (2.7 million Mexican unauthorized migrants) in 1990.

In what follows, we apply the "death registration" method used by Borjas, Freeman, and Lang (1991) to obtain another estimate of the total illegally resident Mexican population and the underenumeration rate for 1990. One of the drawbacks of the death registration method is that it is sensitive to its underlying assumptions. Nevertheless, if the data used to produce the final estimates is carefully selected, the method can be used to obtain annual estimates of the total size of the unenumerated unauthorized population by country of origin.

We use the method to produce a series of estimates of the number of unenumerated unauthorized Mexican-born persons living in the United States in 1990. An estimate is made for several combinations of assumptions regarding the numbers of deaths, different mortality schedules, and sizes of the enumerated Mexican-born population. Table 18 presents estimates of the unenumerated unauthorized Mexican-born population, the total unauthorized population, and the implied undercount rate for each of several combinations of underlying assumptions. The estimates of the total unauthorized Mexican migrant population range from 2.1 million to 2.9 million, with the interquartile range spanning 2.1 million to 2.6 million. The undercount rates corresponding with the interquartile range of estimates ranges from only 14 to 26 percent. The highest estimate of 2.9 million unauthorized migrants implies an undercount rate of only 34 percent. The estimates of the underenumeration rate are higher for males, among whom as many as 40 percent may not have been enumerated. Finally, we note that of the three underlying assumptions, those pertaining to the mortality schedule and the enumerated population tend to exert the greatest influence on the estimates.

In conclusion, the death registration method produces estimates of the underenumeration rate that correspond with other evidence about undercount. Namely, the underenumeration rate for unauthorized Mexican migrants in 1990 appears not to be as high as it was in 1980, most likely is no greater than 35 percent and may even be as low as 15 to 25 percent. In addition, the results corroborate other evidence that the female unauthorized migrant population is better represented in the U.S. Census enumeration than the corresponding male population. The results also show that the death registration method produces estimates that are sensitive to their underlying assumptions. Although the method has a great deal of potential for use in the future, the quality of the estimates could be greatly improved if better information about the mortality rates experienced by the foreign-born population and the enumerated population were available.

Estimates Based on Mexican Data

We are aware that there are is great variety of methodological and conceptual difficulties that have to be addressed in order to arrive at more precise and up to

Table 18

Various Estimates of the Unenumerated Unauthorized Mexican-born Population and Percentage Undercount

Assumptions About: D. Number of Deaths M. Mortality Schedule C.Enumerated Pop'n	Unenumerated Unauthorized Population Est. (in 1,000s)			Total Unauthorized Population Estimate (in 1,000s)			Percentage Undercount

See Table 3 in Volume 2, page 561, for various estimates of the number of deaths, mortality schedules, and the enumerated population.

date estimates of the different modalities of Mexican migration to the United States. In addition to the difficulties in quantifying migration under any circumstances, the very nature of the movement towards the United States complicates the process. Among the most important factor that cloud it is the surreptitious character of much of it, the migrant population's constant renewal, the indeterminate length of migrant's stay in the U.S. and the considerable number of people who return to Mexico, even after long residence abroad.

As we mentioned earlier, measurements carried out in the United States have, among others, two systematic shortcomings: the first one is the difficulty of counting unauthorized migrants, that because of their surreptitious nature avoid detection; the second one is that it is not possible to identify those migrants who go back to Mexico, which can be either "legal" (have not been naturalized yet) as well as unauthorized.

These shortcomings are reflected in the underrepresentation of Mexican migrants in the statistical registers of the Immigration and Naturalization Service, as well as in the Census undercount and in household surveys (in particular the Current Population Survey, CPS). This situation has lead researchers, to make important corrections and adjustments to the original figures by using indirect methods and residual techniques.

On the other hand, the estimates carried out in Mexico face the great difficulty that migrants are not found in their place of origin, either because they are living or sojourning in the United States or because they are on their way there. This feature has restricted the options available to researchers and government statisticians to two methodologies. The first one involves direct measurements from retrospective questions in household surveys that identify labor, permanent and return migrants as well as direct measurement of migration flows through specialized methods for finding, counting and interviewing those either on their way to work or on their way from working in the United States.

The second uses indirect methods, which rely on incomplete or deficient information to estimate a population of interest. When combined with other data, this information can be used to generate two different databases: one that supposedly contains or includes the migrants that are headed toward the United States (P +) and another that excludes them (P -). The difference, or residual [(P +) - (P -)] is attributed to migration. Conceptually, the residual is composed of many kinds of people, which means that the resulting estimate may erroneously include some individuals who have not really migrated, or may exclude some people who have. In general, these approaches have generated plausible results that are consistent with the demographic dynamics of the Mexican population and generally agree with obtained in the United States. This section presents the results of efforts carried out for this project to estimate Mexican migration to the United States based on Mexican data from the 1990s.

Direct Measurement Efforts

The National Survey on Demographic Dynamics

Since the late 1970s, Mexico has carried out various household sampling surveys with the goal of using direct measures to quantify how many migrants move to the United States (for example, the Demographic Survey of Baja California, the Migration Survey in Zacatecas, etc.). The 1992 ENADID (the Spanish acronym), which is the most up-to-date version of these surveys and is used in the country for mid-decade enumerations, improves over these earlier surveys in several important ways. Among these are the following: a) its national coverage; b) its utilization of a considerable sample size (64,000 housing units throughout the country), which permits the use and interpretation of data on a federal scale, c) and its inclusion of various foci, in certain complementary measures, to quantify some of the diverse modalities of the migratory phenomenon (INEGI, 1994).

The ENADID provides a basis for classifying certain Mexican residents as "labor migrants" (people aged 12 years or older who have worked or looked for work in the United States) and others as "return migrants" (people who were habitual reside in the United States, but at the time of the interview were living in Mexico). The measurement of return migration focuses on three retrospective questions traditionally used in Mexico for census gathering (i.e., place of birth, length of current and previous residency, and the place of habitual residency over the past five years). The measurement of labor migration also utilizes retrospective questions to ascertain if a migrant had been a worker or looking for work in the United States and the time period (month and year) of the last movement. As with other similar procedure, this one has several shortcomings: (1) third persons respond for the emigrants, in which case the information is not very precise: (2) the household does not necessarily exist with the same configuration and in the same geographic location during the reference period; and (3) it is impossible to detect emigration of complete families or of people who live alone, since there is no reporting on these people. the survey thus generates an underestimate of the magnitude of migration.

Despite these limitations, the data from the survey are valuable and indicate that of the 85.164 million residents of Mexico in 1992,1.572 million were return migrants and 2.28 million were previously labor migrants in the United States. These figures cannot be added together because the two types of migrants are not necessarily mutually exclusive. In fact, about 1.28 million people are members of both groups, who simultaneously lived and worked in the United States; about 1 million people were "labor migrants"—individuals who do not consider their stays in the United States to be for habitual residence in that country but rather for labor reasons; and about 290,000 migrants did not work in North America during the

Table 19
Mexican-born Population Living in Mexico in 1992 by Living and Work Experience in the U.S.

Living experience in the U.S.		Total	Worked in the U.S.?	
			Yes: Labor Migrants to the U.S.	No: Not Labor Migrants to the U.S.
	Total	85,164,449	2,283,815	82,880,634
Lived in the U.S.?	Yes: Return Migrant	1,572,192	1,282,469	289,723
	No: Not Return Migrants	83,592,257	1,001,346	82,590,911

Source: Estimates of the authors using data from ENADID, 1992

period that they lived there. Together, the three categories of identified migrants (those that lived and worked in the United States, labor migrants who did not reside in the United States and non-working return migrants) total 2.57 million people, which constitutes the number of Mexican residents in 1992 who had migrated to the United States (see Table 19).

If we classify the migrants from the three categories by year of entry to the United States or by year of return to Mexico, the numbers increase over time. This increase is systematic and reflects two results: a) an increasing migration in recent years, and b) the collecting of information in such a way that for each individual only the last movements to the north is recorded, meaning that the verifiable quantities of people who actually migrated in previous periods is understated. Therefore, of the 2.574 million migrants mentioned above, 391,000 (15.2 percent) entered the United States before 1970; 396,000 (15.4 percent) did so between 1970 and 1979; 603,000 (23.4 percent) between 1980 and 1987; and 1.098 million (42.7 percent) between 1988 and 1992. The rest fall under no specific date of entry to the United States. Of those returning to Mexico, 349,000 (13.6 percent) did so before 1970; 331,000 (12.9 percent) did so between 1970 and 1979; 587,000 (22.8 percent) between 1980 and 1987; and 1.22 million (47.4 percent) between 1988 and 1992. The rest do not fall under any specific date of return to Mexico. Table 20 shows the breakdown of the 1.22 million migrants that returned to Mexico between 1988 and 1992 by year of return for each one of the 3 categories mentioned.

Table 20
Mexican-born Population Living in Mexico in 1992 that Lived and/or Worked in the United States and Went Back to Mexico between 1988-92, by Year of Return from the United States

Work and/or Residence Status in the U.S.	Year of return to México					Total
	1988	1989	1990	1991	1992*

Lived but not worked in the U.S.***	14,775	28,325	23,532	40,120	62,008	168,760

Source: Estimates of the authors using data from ENADID, 1992

*Labor migrants for 1992 include 47,767 persons that at the time of the interview where working in the U.S. as well as 65,205 labor migrants that commute to work daily to the U.S.
*These figures refer to the year of return to Mexico after working in the U.S.
**These figures refer to the year of return to Mexico after living in the U.S.

For each reference or survey period there are differing groups of migrants who enter or leave the United States. These differences are due to varying periods of residency in North America. For example, we can estimate that between 1988 and 1992, a total of 1.098 million people entered the United States (an annual average of 220,000) and 1.220 million people returned to Mexico (an annual average of 244,000 people). Of these two figures respec tively, 707,000 and 786,000 fall under the category "lived and worked" in the United States, with an annual average of 141,000 and 157,000, respectively; 250,000 and 265,000 are those that "worked but did not live" in the United States, with an annual mean of 50,000 and 53,000; and 140,000 and 169,000 are those who "lived but did not work" in North America, with an annual average of 28,000 and 34,000. The difference between outgoing and return flows is explained by differing periods of U.S. residency. Those who traveled to and returned from the United States during the 1988-1992 interval include people who left the United States in the reference period but had entered the country earlier.

The ENADID results also portray some demographic and socioeconomic characteristics of the migrants. Those who returned to North America between 1988

and 1992 (1.22 million) can be differentiated by the three migratory categories above, showing that: the labor migrants (the "pure" ones and those who "worked and lived" in the United States) are predominantly men (more than 80 percent). In contrast, women represent the majority (60 percent) of the migrants who did not work, indicating their greater role as companions; the labor migrants were basically young adults (more than 65 percent of those observed were between the ages of 20 and 39), while those that did not work in the United States are in large part adolescents and children (about 60 percent are less than 20 years of age); the labor migrants are predominantly heads of families (about 60 percent), while in the majority of cases the spouses and children of the migrants did not work; of the "pure labor migrants" and those who did not work, more than 50 percent were living in the traditional zone of emigration (west central Mexico) during the time of the interview, close to 25 percent were in the northern states, and between 15 and 20 percent were in the central region. Those migrants that worked but did not live in the United States were interviewed primarily in the northern region (53 percent), the traditional zone (24 percent) and the central area (20 percent). In all categories, there was little participation from those residing in the southeast (between 1.5 percent and 3 percent).

The ENADID results also provide a basis for determining how many people left Mexico to reside in the United States. Interviewees were asked if one or more members of a household went to live in the United States in a specific period of reference. Once identified, emigrants were questioned about their characteristics (age, gender, family relations, date of emigration, current place of residency). The question on "current place of residency" identifies emigrants who stay out of the country as well as those who are return migrants. Return migrants were questioned about their date of return. As with other similar procedures, this one had limitations: a) it relies on third person responses for the emigrants, in which case the information may not be accurate; b) the household did not necessarily exist with the same configuration and in the same geographic location during the reference period; and c) it is not possible to identify emigration of complete families in transit or people living alone but in transit, since no one was at home to be interviewed. In all, these limitations generate an underestimate of the magnitude of permanent emigration. Nevertheless, the data thus established provide a pool of knowledge, offering valuable information about the phenomenon. For example, the major results were:

- 1.823 million people left Mexico for the United States between January 1988 and November 1992, of whom 972,000 continued to live in North America at the time of the interview (permanent emigrants) and 851,000 returned to Mexico after living in the United States (return immigrants).

- Table 21 shows the breakdown of these migrants by the year of departure to or return from the U.S. We can see that emigration appears to increase over time: 226,000 left in 1988 (130,000 lived in Mexico and 96,000 still resided in the United States), 310,000 in 1989 (177,000 and 133,000, respectively), 354,000 in 1990 (201,000 and 153,000), 351,000 in 1991 (186,000 and 165,000) and 581,000 in 1992 (156,000 and 425,000). This could be due to various combinations of four circumstances: a) a possible real increase in emigration to the United States; b) a reduction in the permanent return emigrants in later years (there is a tendency to remain indefinitely in the United States for about 40 percent of migrants, but the percentage of those only remaining rises after at least three years); c) the existence of a repetitious movement to the United States, which diminishes the number of people from previous years because the single migrants are placed in the most recent migration; and d) the greater impact of questions about more recent events.
- With the goal of minimizing the distorting effect of the period of residency in the United States and to have a better approximation of the magnitude of the phenomenon, we obtained the annual averages of the years 1988-1992. These figures indicated that in the 1988-1992 reference period, an annual average of 365,000 people traveled to the United States and established residency, of which 195,000 still lived in that

Table 21
Mexican-born population that went to live in the United States between January 1988 and November 1992, by year of migration and year of return to Mexico

Year Migrated U.S.	Went back to live in Mexico						Live in the United States	Total
	Total	Year of return to México

Total	850,722	41,708	105,605	165,522	242,468	295,419	972,177	1,822,899

Source: Estimates of the authors using data from ENADID, 1992

country at the time the survey was carried out and 170,000 had already returned to Mexico. This latter figure, although smaller, is similar to the average mean return migration previously estimated for the same period under questioning about place of birth and place of previous residency (that is to say, 191,000 people, excluding "pure labor migrants").

- The distribution of permanent emigrants and return immigrants underscores a well-known profile: a larger number of men, a structure marked by youthful age (concentrated in the first years of economic activity), a higher proportion of heads of households among the return migrants and of children among the permanent emigrants; and, in general, a distribution by place of origin in Mexico that is similar to that previously described.

The Migration Survey for the Northern Mexican Border

The Migration Survey for the Northern Mexican Border is a continuing method of generating data using procedures for quantifying mobile populations. In this sense, the migrants are observed while they are traveling to work in the United States or during their return to Mexico. When they arrive at Mexican border towns and they gather in specific places in those cities, as for example bus or railroad stations, airports or customs check points, it is then possible to select places for the enumeration, sampling and interviews (Corona 1997; Santibañez 1997).

A first phase of this survey began March 28, 1993 and ended on March 27, 1994. The second phase spanned all of 1995. It conceptualized labor migrants as units of movement observed at certain times and places in their migratory cycles and identifies various target populations. The survey contributes useful information that helps to answer the following questions: What is the magnitude of the flow of Mexican labor to the United States in a specific reference period and how does it vary in each phase of the survey? Has the labor flow increased, decreased, or remained constant in the two phases of the survey? Which are the observed changes in the composition of the flow that could be relevant to explaining the observed changes in the magnitude of the flow? What proportion of the labor flow is documented labor and what proportion is undocumented? How have these two components of the flow evolved between the two survey phases or references periods? What is the net outmigration when we compare outward flow to that of the return flow in each phase? How has the net outmigration changed between the two survey phases or between the two reference periods? What does this outmigration signify?

In answer to these questions, we present some results based on the Northern Border Survey. We examine first the magnitude and characteristics of the outward flow (south-north flow) and then the return flow (north-south) flow. The available data reveals that between the two phases, the flow toward the United States was considerably reduced, rising to approximately 792,000 people in Phase One and dropping to nearly 543,000 in Phase Two. If we analyze the data from the Northern Border Survey just for the years 1993 and 1995, we obtain a similar conclusion. The reduction in flow does not have a single interpretation. To identify the significance of our results, we must consider that migrants must have in common two basic conditions in order to be counted as part of the same flow: a) they must reside in Mexico; b) and they must be headed toward the United States to work or look for work. A member of the labor flow to the United States can be considered the same whether he or she does not return to Mexico and "settles" in the United States or whether he or she stops traveling periodically to that country to work or look for work.

With these observations in mind, the previously mentioned trends can be interpreted in three different ways. First, the observed decrease in the magnitude of the labor flow to the United States could be due to a reduction in the number of people who form the group from Mexico. Among other factors, this would be associated with a) the difficulties (real or perceived) of entering the United States as an undocumented migrant; b) the difficulties (real or perceived) of encountering employment there; and c) an increase in the direct or relative costs of movement from the Mexican interior to the United States, which could be from loss of buying power among potential migrants and from the devaluation of the peso relative to the dollar. Second, the reduction in the magnitude of the labor flow to the United States also could be attributed to large outmigration during previous reference periods. These migrants may have established residency in the United States or prolonged their stay, a fact that itself can be associated with, a) the difficulties (real or perceived) of finding adequate remunerative employment in the migratory zone of origin during a profound economic crisis; b) the strengthening of the role played by the social and family networks in the United States; and c) the growing obstacles to leaving and returning to the neighboring country because of restrictive immigration measures, particularly the strengthening of the U.S. Border Patrol. Third, the trend could be a combination of the two previously mentioned possibilities. Specific weights for each factor would have to be determined in the future.

We questioned whether the Migration Survey for the Northern Mexican Border contained sufficient data for testing our hypotheses. Our idea was that identifying eventual changes in the internal composition of the labor current directed at the United States would shed light not only on the characteristics of those who enter or stay within the labor flow, but also those who leave it between phases. With

this idea in mind, we examined socioeconomic, demographic and family characteristics of labor migrants, attempting to identify the most relevant changes occurring between research phases or reference periods, the available data showed among other things, that:

- the labor flow continues to be predominantly masculine;
- the migratory flow consists primarily of young people and adults of economically active ages
- the members of the labor flow in general worked in Mexico before initiating their trips to the United States, although the relative weight of those who lacked jobs increased in the recent period;
- most labor migrants come from the urban zones of the country (15,000 inhabitants or more), although in recent years the number of migrants from rural areas has increased;
- the labor flow continues to originate predominantly in the federal entities that make up the traditional emigration zone (their relative weight increased in the recent period), the numbers coming from northern, central and southern Mexico had decreased significantly.
- the state of California is the principal destination for labor migrants, which also was characteristic of the earlier reference period;
- the number of labor migrants who intend to stay in the United States for more than six months is increasing and the number who want to stay for shorter periods is decreasing.
- the flow contains people who generally live alone or in other cases are accompanied by people—family or non-family members—of 12 years of age or more;
- the majority of labor migrants go to the United States regularly, although in the most recent survey period this tendency lost relative weight in the flow;
- the migratory flow consists of many workers who generally did not have documents to enter or work in the United States, a characteristic of labor flows in earlier periods;
- first-time migratory workers increasingly lack documents for entering or working in the United States;
- workers who habitually travel to the United States for work increasingly lack entry or work documents as well.

- Summarizing, the flow of workers towards the United States not only decreased in size, but there where also important changes in its characteristics. Some of these changes are very likely the result of migrants with specific characteristics dropping out of the flow (e.g., those with migratory experience in the United States, or those authorized to work).

In the case of the return flow from the United States (north-south) we observed that an important decline in absolute values, from more than 624,000 to 433,000 between Phases 1 and 2. This data is similar to data for the last three quarters of 1993 and 1995, (518,000 migrants for 1993 down to 296,000 migrants for 1995).

The demographic and socioeconomic characteristics of the return migrants are generally similar to those of people in the south-north flow. In addition to the already mentioned reduction in the magnitude of the return flow, we noted that:

- the flow is formed primarily by men, although in recent years the relative weight of female participation has increased;
- first-time members of the return flow are concentrated within the economically active ages (between 12 and 34 years), but important changes were detected in the age distribution between reference periods;
- as reflective of what took place in their outbound voyage, the return flow is composed of people that generally undertake the trip alone or are accompanied on their return trip by people—family or non-family members—of 12 or more years of age;
- the majority of labor migrants stated that on their most trips to the United States that they had entry documents, although the relative weight of those individuals who did not have them grew. As a result, the flow has a more balanced participation between the two groups;
- labor migrants with work documents on their most recent trip to the United States were roughly equal to those without them in the earlier survey period. In the most recent survey period, the number without work documents dominated the flow;
- about 85 percent of first-time return migrants do not have work documents;
- about 87 percent of labor migrants did not need the services of a pollero or coyote to enter the United States on their most recent trip; this is a significant change from earlier periods;

- about 70 percent of return migrants had been to the United States only once or twice before. This is consistent with trends from earlier periods;
- as with the south-north flow, many return migrants lack U.S. entry or work documents and the number of first-time migrants without them is increasing;
- but still, the majority of migrants with previous U.S. migratory experience had entry or work documents, although the relative weight of those without documents has grown significantly.
- the majority of the return migrants are from urban areas of Mexico;
- the migrants who come from the states of traditional emigration constitute the largest portion of the return flow although their relative weight has declined in recent years;
- California has been displaced in recent years by Texas as the primary state of residence for migrants to the United States, and is identified as such by a growing proportion of migrants;
- the main portion of the return migrants worked in Mexico before undertaking their most recent trip to the United States, but recently the relative weight of this group has diminished significantly;
- the largest part of the return flow did work during their most recent stay in the United States (about eight out of every 10), although a slight reduction is estimated for the relative participation of this group;
- a large number of return migrants sent monetary remittances to Mexico, although the relative weight of this group has diminished enough to no longer represent the majority in the observation period;
- the migrants declared as their principal reason for returning to Mexico, in order of importance: 1) to visit their families; 2) to rejoin the work force in their respective places of habitual residency; 3) because they had not worked in the United States; 4) because they had been apprehended by the U.S. Border Patrol. In recent years, the number of migrants who said they were apprehended has increased significantly and those returning to visit families.

Available information indicates similar demographic and socioeconomic characteristics had decreased between the groups of return labor migrants and departing labor migrants. But one difference in the most recent flow is the decline of the relative weight of the return migrants who originated in the traditional states of emigration and those from rural areas (in contrast to the growing participation of

those who come from the northern region and the urban zones of the country). This suggests lengthier stays in the United States among those migrants originally from the north or the urban zones. And they may be supported by more solid social networks and family linkages between origin and destination.

The difference between the figures of the two directions of the flow represent the net migration, which may produce either a gain or a loss of population, which is due almost exclusively in the labor migration flow during the period of reference. In the first round the net balance was negative and reached some 167 thousand people, whereas in the second round it was also negative and reached 109 thousand, which is 65 percent of the balance of the earlier round.

Indirect Measurement Efforts

Because direct measurement of migration to the United States is so difficult, researchers have largely relied on indirect measurement and have developed a number of methodologies for estimating migratory flows. Indirect measurement procedures have been refined over time with new types of statistical databases and with new data on specific aspects of migration. Nevertheless, the accuracy of the measures still depends on certain assumptions about an "invisible statistic"—the migrant population—that cannot be verified through available information sources. One way to confront this limitation is to make changes in the theoretical assumptions used and then analyze the variation in research outcomes under the modified assumptions. Even though the procedures for indirect measurement have little to offer in terms of definitive or conclusive results, the measurements have considerably reduced the margin of uncertainty about the magnitude of the migration phenomenon. (Castro 1990; CONAPO, 1992a, 1992b, 1995a, 1995b; Corona, 1991, 1994, 1995; Partida, 1990). The estimates from indirect measures that have been based on data from Mexico (see Table 22):

- indicate that the loss of Mexican population from international migration has been systematic since 1960;
- establish limits to the estimates of permanent Mexican migration to the United States between 260,000 and 290,000 in the decade of 1960-1970; between 1.2 million and 1.55 million during the decade of 1970-1980; and between 2.1 million and 2.6 million in the decade 1980-1990. These figures indicate that the net annual flow has increased with the passage of time, going from about 28,000 in the decade of 1960-1970, to close to 140,000 in the following decade and at 230,000 in the decade 1980-1990.
- confirm that the estimated magnitude of the flow in the past decade is

considerable and that the effect of this flow on the dynamic of demographic growth in the country is perceptible.

- The results of these indirect measures of the net migration flow between Mexico and the United States are very reasonable, they are consistent with the demographic changes of Mexico's population and they are in general agreement with the estimates carried out with United States data sources.

With the idea of counting with an indirect measure of migration between Mexico and the United States during the most recent period, (for the five years between 1990 and 1995), in research carried out for this report we used a residual procedure (that is derived from the use of a balancing equation) with information from the Population and Housing Count of 1995 (published at the end of April 1996 and referring exclusively to the total inhabitants of Mexico classified by sex and federal entity) and data from the Eleventh General Census of 1990. The main results obtained from this

Table 23
Estimates of the Mexico's Net International Migration Flow between 1990 and 1995 by State of Residence

State of Residence[1]	Total	Annual average
Total	-1,387,481	-277,496
North	-338,584	-67,717
Traditional	-664,824	-132,965
Central	-383,792	-76,785
Southeast	-281	-56

[1]State of Residence:
North: Baja California, Baja California Sur, Coahuila, Chihuahua, Nuevo León, Sinalóa, Sonora and Tamaulipas.
Traditional: Aguascalientes, Colima, Durango, Guanajuato, Jalisco, Michoacán, Nayarit, San Luis Potosí and Zacatecas.
Central: Distrito Federal, Guerrero, Hidalgo, México, Morelos, Oaxaca, Puebla, Qurétaro and Tlaxcala.
Southeast: Campeche, Chiapas, Quintana Roo, Tabasco, Veracruz and Yucatán.

procedure (for the national totals) are the following: For 1990-1995 net outmigration was 1.387 million people, with an almost equal participation by sex (694,000 men and 693,000 women) and the net count gave a distribution by groups of entities located inside the known migratory pattern (47.9 percent in the traditionally highest zone of migration; 24.4 percent in the northern states and 27.7 percent in the central entities). The figure of 1.39 million people is an estimate of net outmigration during the five-year period between 1990-1995, which is equivalent to an annual average of 277,000 people (see Table 23). This estimate (1) is substantially higher that that observed during the decade 1980-1990; (2) agrees with that developed independently by the Mexican Population Council (CONAPO); and (3) is relatively close to the figure of 316,000 estimated with U.S. data sources in research conducted for this report. It also should be noted that this estimate is also higher than that directly derived from ENADID, which in turn suggest that an important number of Mexican migrants lived alone in their places of origin before leaving to the U.S. or left the country with all members of their households.

Other results obtained from this procedure (for the national totals) are the following:

- If the natural growth (and the interstate migration) of the five-year period is correct and if the states of the southeast do not have significant migration to the United States, then the positive outmigration encountered for these six entities (35,000 women and 70,000 men) constitutes a better measurement in the enumeration of the 1995 count than in the enumeration of the 1990 census. The census population, corrected for undercounts stemming from the 1990 census (0.52 percent for the total, 0.70 percent for men and 0.34 percent for women), was used to obtain an estimate of net outmigration of 1.166 million emigrants, with a balanced participation of men and women (576,000 male emigrants and 590,000 female emigrants) and a distribution by groups of origin (54.2 percent coming from the states with traditionally high migration; 25.3 percent from northern states and 20.5 percent from entities located in the center of the country), which is consistent as much with the migratory trend up to 1990 as with the data from the survey carried out for the period 1990-1995.
- The second estimate was carried out using the same operations and considerations from the previous calculation, but with some modification. Instead of calculating the population by gender and entity in 1995 as a sum of the residents in 1990 plus the natural increase (and increase due to internal migration), the population is determined as a product of the residents in 1990 by a factor that accounts for the growth in declining international migration. This was the basis for establishing a percentage of undercoverage from the 1990 census that was almost double the figure used in the previous estimate (0.92 percent for the total, 1.22 percent for men and 0.63 percent for women). With this method, the net outmigration rose to 1.387 million people, with an almost equal participation by gender (694,000 men and 693,000 women) and the new count gave a distribution by groups of entities located inside the known migratory pattern (47.9 percent in the traditionally highest zone of migration; 24.4 percent in the northern states and 27.7 percent in the central entities).

The two previous estimates did not yield such disparate results, in spite of the utilization of different assumptions about the undercoverage of the 1990 census. The differences rose to 19 percent of the total, 20.5 percent for men and 17.5 percent for women. Nevertheless, if the differences between one calculation and the other with respect to the distribution of outmigration by groups of entities are accurate, the differences are not tremendous for the northern states and for the states of traditionally high migration (14.8 percent and 5.1 percent, respectively), but the difference is tremendous for the central entities (60.7 percent). This marked

contrast between the results of the two estimates shows the need to carry out a more detailed analysis of the same, revising the internal coherency, in order to choose one of these estimates as the definitive product of this residual methodological application. The figure of 1.387 million people corresponds to our estimate of net outmigration during the five-year period between 1990-1995, which is equivalent to an annual average of 277,000 people. This quantity, slightly higher than that observed during the decade 1980-1990, results in a negative annual international migration rate of 0.31 percent.

Immigration to Mexico

Immigration to Mexico is not very large. Table 24 shows the number of foreign immigrants that lived in Mexico in 1970, 1980, 1990 and 1992 by sex and country of birth. During the decades of the 1970s and 1980s, annual average increases of 7,000 immigrants were reported. The 1990 Census data indicated that by 1990, a total of 340,00 foreigners resided in Mexico, which represents scarcely 0.42 percent of the country's inhabitants. Data from the National Survey of the Demographic Dynamic reinforced this estimate, but also indicated that in recent years, immigration to Mexico has intensified substantially (between 80,000 and 100,000 in the period between March 1990 and November 1992, inclusive). The demographic and socioeconomic characteristics of migration to Mexico are:

- a similar proportion of men and women immigrated, and did not show significant variation by place of origin or by period of entry to Mexico;
- the United States is, by far, the principal country of origin for the immigrants (more than 50 percent of the immigrants are natives of that country), followed by natives of Central and South America, and after them, in lesser numbers, natives of Europe, Asia and Africa;
- the composition by age differs by place of origin. The natives of the United States exhibit a peculiar distribution: more than 40 percent are less than 10 years of age and almost 30 percent are children or adolescents between 10 and 19 years of age. This fact seems to be associated with return migration of Mexicans—who bring with them children born in the United States. The apparent intensity of immigration observed between 1990 and 1992 appears to explain, in large measure, the increased numbers of children. In contrast, the immigrants of non-American countries display a structural aging and the Central and South Americans conform to a youthful age profile.
- 10 geographic entities in Mexico attract about 80 percent of the immigrants: Baja California, Chihuahua, Nuevo León and Tamaulipas

* Total foreign born divided by total resident population in Mexico (per 100)

in the northern border region; Guanajuato, Jalisco and Michoacán in the plateau region of northern Mexico and the west; the Federal District and the state of Mexico in Central Mexico; and Chiapas in the southeast. The distribution of the immigrants in the 10 areas varies by country of origin. The natives of the United States reside basically in the north and the west, also zones of outmigration to North America (the later reinforces the hypothesis that part of the immigration coming from the United

States is linked to migration from Mexico to the United States). In the Valley of Mexico, more than 60 percent of immigrants were born on the American continent. About 40 percent of the immigrants living in Chiapas come from the south, especially from Central America.

The flow of immigrants from Central America have received special attention in the past several years because of their growing importance and apparent regional impact on Mexico's southern border. The available research on this issue has progressively characterized the typology of these flows, pointing to the following: a) the seasonal agricultural workers; b) the Guatemalan refugees; and c) the undocumented transmigrants.

- the flow of agricultural workers is directed principally at Chiapas. Measuring these workers has been difficult because a significant number of them (the proportion cannot be determined) habitually move without documents. Past estimates, coming generally from migration officials, are derived more from individual observation and practical experience than from procedures that rely on analytical and empirical bases. More recently, the efforts of migration authorities to standardize this flow has generated some additional data, but not enough to estimate the flow reliably. The most recent migration records identify between 50,000 and 75,000 documented entries annually into Mexico (although a single entry can include several people). This figure is derived from an inferior threshold, however, because it does not include undocumented entries, which at the present time are impossible to quantify.
- the Guatemalan refugee populations, which is encamped at Chiapas, Campeche and Quintana Roo, rose at the beginning of 1996 to about 32,000 people. But it is believed that an undetermined additional number of refugees exist but are not known as such because they can be found scattered throughout the territory and because they arrived in Mexico during the 1980s in conditions very similar to those of refugees established in the camps.
- the undocumented transmigrants are those people who have penetrated the national territory with the idea of moving to a third country. As with the migration to the United States, the surreptitious nature of this movements obscures the ability to measure them. We can rely on only those figures that match the number of deportations and expulsions carried out by migration authorities. These figures only give an indirect idea of the significance of this movement. The expulsions have been constantly rising and demonstrate two points of inflection: one is in 1980, when the expulsions exceeded 10,000 actions, and the second is

in 1990, when the figure surpassed 100,000 annual actions. Almost all of the expulsions carried out in the past several years have been systematically against migrants coming from Guatemala, El Salvador and Honduras.

Summary of Results from Estimating Procedures and Update to 1996

As of 1980, stock and flow estimates of the unauthorized migrant population tended to be unreliable due in part to lack of methodologies for correcting for biases in the available data sources. For instance, better methods had to be developed in order to make more valid estimates of in-flow on the basis of INS apprehensions and nonimmigrant entrance/exit forms. Also, early analytic estimates tended to be inconsistent in their assumptions, methodologies, and consequently, in the populations they described. Hence, the various estimates were difficult to compare and evaluate (Bos, 1984). Finally, reviewers (Siegel, et al., 1980; Hill, 1985b) found that most early analytic estimates of stock and flow were sensitive to their underlying assumptions. More complete data about the foreign born and the unauthorized migrant population had to be obtained in order to better support underlying assumptions, such as those made about undercount (Goldberg, 1974; Heer, 1979) and death rates (Robinson, 1980). As a result of these and other problems, Siegel and his co-authors concluded in 1980 that there were "currently no reliable estimates of the number of unauthorized residents in the country or of the net volume of unauthorized immigration to the United States in any past recent period" (1980). Nevertheless, they conceded that the analytic studies supported the view that by the end of the 1970s, 2.5 million to 5 million unauthorized migrants and 1.5 million to 2.5 million unauthorized Mexican migrants resided in the United States.

The residual studies conducted during the 1980s obtained results at the beginning of the 1980s that tended toward the lower end of this range, subject of course to considerable uncertainty about the fraction of the unauthorized Mexican migrant population not enumerated in the official U.S. Censuses and surveys on which they were based, as discussed at length above. The results of these studies also showed the effects of IRCA's legalization programs, which removed substantial numbers of undocumented migrants from the estimates of stock. They also revealed that the unauthorized migrant population (both overall and from Mexico) continued to grow annually during the 1980s, diminished in total numbers only by the legalization programs of IRCA.

Several broad classes of factors affect the significance and meaning of these (and in fact any) estimates. One, of course, is their accuracy. To what degree can we be confident that the figures reflect the sizes of the populations they are intended

to represent? While uncertainties remain (as noted in discussions above), there is little question that the results of research on the magnitude of stocks and flows during the 1980s have narrowed considerably the range of plausible estimates. However, because of data gaps (e.g., the deletion of I-53 registration system, inadequate information on emigration, and little empirical data on the undercount of the unauthorized population), estimates during the 1990s that rely on residual approaches may be subject to increasing uncertainty, and thus perhaps are increasingly likely to generate broad ranges of estimates (Woodrow-Lafield, 1996).

Another factor that effects the significance of estimates is the context in which they occur. Estimates are most appropriately viewed not in isolation, but in relation to other kinds of changes, including population changes. We discussed above the policy significance of possibly shifting proportions of EWIs and visa overstayers. More broadly, it is of interest to examine how the estimates of unauthorized Mexican migration compare to population size generally in both the United States and Mexico. The estimated enumerated unauthorized Mexican population (1.131 million) in 1980 represented about 51 percent of the total Mexican-born population in the United States, 8 percent of the U.S. foreign-born population, 12.9 percent of the total Mexican-origin population, 0.4 percent of the total U.S. population, and 1.7 percent of the total Mexican population.

What evidence is there about the size of the unauthorized Mexican migrant population during the 1990s? Estimates of Mexican unauthorized migrants should readily square with evidence about (1) the overall size of the Mexican-born population in the United States, (2) estimated rates of underenumeration in the legal unauthorized populations, and (3) estimates of the size of the legal Mexican-born population. A 1996 figure for unauthorized Mexican migrant stock may be constructed by starting with the overall size of the enumerated Mexican-born population from the March 1996 CPS of 6.68 million. Based on the evidence in Hogan and Robinson (1993) and Van Hook and Bean (1997) about undercount rates, we set plausible underenumeration rates for the legal and unauthorized Mexican populations at 4 and 12 percent respectively. Consistent with the evidence that about 700,000 SAWs were in the United States in the 1990s, we also adopt a mid-range estimate of 4.8 million legal Mexican immigrants (Woodrow-Lafield, 1997). Given these values, the *enumerated* number of legal immigrants is estimated as 4,608 million (4.8 x 0.96 = 4.608) and the number of unauthorized immigrants as 2.35 million (6.679 - [4.8 x 0.96]/0.88 = the number of unauthorized migrants = 2.35). Placing a 90 percent confidence interval around the overall total of 7.15 million Mexican-born persons in the United States in 1996 (obtained by adjusting for undercount) adds and subtracts about 150,000 from each side of this value, giving and estimated range of 7 milliion to 7.3 million total Mexican-born persons in the United States. In 1996, then, a figure of 2.35 million unauthorized Mexican-

born migrants would represent 37.8 percent of the U.S. Mexican-born population, 10.2 percent of the U.S. foreign-born population, 11.6 percent of the Mexican-origin population, 0.8 percent of the total U.S. population, and 2.3 percent of the Mexican population.

Characteristics of Migrants: Mexicans in the United States

Jorge A. Bustamante, Guillermina Jasso, J. Edward Taylor & Paz Trigueros Legarreta

Introduction

The objective of this chapter is to present a comprehensive statistical portrait of Mexicans in the United States, summarizing their demographic and socioeconomic characteristics and examining changes in these characteristics over time.[1]

The observed characteristics of migrants are a product of the selectivity of the migration process, reflecting behavioral mechanisms and the influence of personal, household, and societal variables on migration decisions and outcomes. They are the first determinants of international migrants' impacts on both origin and destination countries.

Migrant characteristics partly reflect the characteristics of the population-at-large from which migrants are drawn. For example, if migrants are drawn randomly from a population that becomes increasingly educated over time, the average education of migrants will increase; if randomly drawn from a population that is aging, the average age of migrants will increase, etc.

However, the process that selects people into and out of migration is not random. Forces of labor supply and demand at home and abroad shape the economic returns to skills and other characteristics, encouraging some people to migrate and others not to. Contacts with individuals at migrant destinations reduce both the economic and noneconomic costs of migrating, while increasing the benefits. The spread of "migration networks" may make migration a self-perpetuating process less selective of individual characteristics; as a result, the characteristics of migrants and nonmigrants may become more similar to each other over time. Studies document cases in which statistical differences between migrants and nonmigrants from specific locales in Mexico, which at one time were pronounced, have faded or disappeared. Economic changes in migrant-sending areas may profoundly influence migrant characteristics, e.g., by altering the returns to individuals' specific human capital characteristics in the United States relative to the place of origin or to migrant destinations in Mexico, or by reducing expected incomes in Mexico by a large enough margin to tip the scales in favor of migration for new groups of individuals with new sets of socioeconomic characteristics.

Just as the people who migrate tend to be different from those who do not, so, too, the characteristics of migrants in different migration statuses differ. Characteristics of short-term, temporary migrant workers tend to be different from those of more settled migrants in the United States. Among relatively settled migrants, the characteristics of naturalized citizens (arguably the most settled group) differ from those of noncitizens. Among legal immigrants, characteristics differ by visa type. In many cases, these differences in characteristics by migrant status are striking.

The migration process is dynamic: the forces selecting people into and out of migration change over time. The spread of migration networks, which make migration accessible to an increasingly broad and diverse population in Mexico, is but one example. Data from a variety of sources indicate that socioeconomic and demographic characteristics of migrants vary across migrant cohorts and at different stages of sending areas' migration histories. Migrants, themselves, may change as well—in terms of legal status, labor-market experience, migratory behavior, human capital, etc.

The changing characteristics of Mexico-to-U.S. migrants have important long-run implications for both the United States and Mexico. Changes in who migrates to the United States and who remains in Mexico, as well as in who settles and who eventually naturalizes in the United States and who—eventually or intermittently—returns to Mexico, have potentially far-reaching ramifications for the impacts of Mexican migration on U.S. labor markets and on economic development in Mexico.

The selectivity of migration, and thus migrant characteristics themselves, are inextricably linked to determinants of migration. For this reason alone, migration theory cannot be ignored if one hopes to understand migrant characteristics and

their changes over time. However, there are other compelling reasons not to carry out our statistical analysis in isolation of migration theory. Researchers' theoretical frameworks (and governments' policy priorities) shape the collection of data on migrant characteristics. They determine, for example, whether households in the U.S., households in Mexico, or migrants at the border will be the unit of analysis for data collection. In addition to *who* is surveyed, they also determine *what* information is collected. The U.S. Census, the U.S. Immigration and Naturalization Service, the National Agricultural Worker Survey (NAWS), the COLEF surveys, ENADID, and village surveys in Mexico all provide data on different Mexico-to-U.S. migrant subpopulations and on different variables, often with little overlap. Generalizing from these disparate data sources to construct statistical profiles of different migrant groups requires understanding the theoretical frameworks and policy concerns that "produced" the data. Although *theories* of migration are not the focus of this chapter, we nevertheless draw from theory, where appropriate, to interpret and compare our findings on migrant characteristics derived from different data sources.

We also undertake, wherever possible, comparisons between migrants and other groups as background for later chapters. Assessment of the determinants and consequences of migration requires comparing the characteristics of migrants to the characteristics of other major actors and groups. For example, a full assessment of the determinants and consequences of migration from Mexico to the United States would require not only description of the characteristics of Mexicans who reside in the United States but also comparisons with: (i) Mexicans who remain in Mexico; (ii) in-migrants to Mexico, especially those from the United States; (iii) Mexican out-migrants to countries other than the United States; (iv) nonmigrants in the United States; (v) out-migrants from the United States, especially out-migrants to Mexico; and (vi) in-migrants to the United States from countries other than Mexico.

Unfortunately, data constraints do not permit such detailed comparisons. No single data set from either side of the U.S.-Mexico border provides reliable information on all of the variables or comparison groups that are the focus of our research. Because of this, characteristics of Mexican migrants have to be pieced together from a number of data sources in the United States and Mexico. Data deficiencies sometimes compromise the reliability of estimates, and they put a premium on migration theory and on developing and using statistical techniques capable of addressing related estimation biases (as well as on developing new data collection initiatives).

Our analysis of migrant characteristics is based partly on a review of existing studies. However, it also draws heavily from original analysis using the most reliable data available in the United States and Mexico. Many of our findings are presented here for the first time. The U.S. data we use include U.S. Census data,

INS administrative data on legal immigrants and apprehended unauthorized migrants, preliminary data from the New Immigrant Survey (NIS) of legal immigrants admitted in 1996, agricultural-worker survey data, and data from the Colegio de la Frontera Norte (COLEF)/USC Los Angeles Project. The Mexican data sources include the Mexican government's 1992 National Survey of Demographic Indicators (ENADID), the COLEF Survey of Migration at the Northern Border (EMIF) and Zapata Canyon project, and household surveys conducted by researchers from Mexico and the United States, primarily in rural Mexican communities.

To date, little research has been conducted on the selectivity of international migration, and the research that has been carried out has focused primarily on "human capital" characteristics of migrants: schooling, skills, and demographic traits. We believe that an expanded set of characteristics is appropriate for this study, including characteristics of individual migrants (human capital, or migrant characteristics), of the families from which migrants come (household capital, or family characteristics), and of the migration process, itself ("migration capital," including migration experience of both the individual and the family of which he or she is part). All three sets of characteristics interact in complex ways to shape the impacts of migrants in their communities of origin and abroad as well as influencing future migration propensities.

Major Conclusions

Our major conclusions include the following:

First, the Mexico-born population in the United States is not homogeneous; it is comprised of many different behavioral and legal-status subgroups. Some migrants are short-term, temporary or "circular" (i.e., sojourners, whose habitual residence is in Mexico), while others are relatively long-term or settled (habitual residents of the United States). These largely behavioral categories map imperfectly onto migrant legal-status categories. For example, circular migrants include unauthorized (or undocumented) migrants, legal temporary agricultural (H-2A) workers, and other legal temporary residents, including workers with H-1 visas, students, and tourists. The settled Mexico-born population includes some legal temporary residents and unauthorized migrants who spend long periods of time in the United States, as well as legal permanent resident aliens, some of whom are naturalized citizens. Both these groups are diverse, ranging in skills from agricultural workers to Ph.D. scientists and symphony musicians.

Second, measured characteristics differ—in some cases markedly—not only among these different Mexican migrant subgroups, but also across data sources focusing on different groups (see Table 1).

NOTES: Subsets identified in the data are denoted by closed rectangles. Missing rectangle denotes the absence of persons in the data set currently in that legal status. The set of deportable migrants includes legal nonimmigrants who violate the terms of their visa and entrants without inspection. The "other Mexican household surveys" discussed in the text resemble ENADID in their information on legal status.

Most short-term, temporary or "circular" migrants are males (73 to 94%, depending on the data source), young (28 to 32 years of age), with low levels of schooling (typically between 5 and 8 years), and a disproportionately strong attachment to U.S. agricultural jobs (up to 53% of circular migrants are employed in agriculture). They have a very high labor force participation rate compared to other U.S. groups (81 to 89%) but low earnings (as little as $185 per week) and high poverty rates (more than one half of families in some circular migrant subgroups have incomes below the poverty line). Very few (as few as 7 percent) speak English well.

Circular migrants tend to be selected from the middle-to-lower ranges of Mexico's socioeconomic hierarchy. This selection process originated with the recruitment of low-skilled Mexican workers by U.S. employers for seasonal jobs, mostly in agriculture. It was facilitated by the long and historically porous border between Mexico and the United States, which put U.S. labor markets within reach of individuals with limited financial resources in Mexico; by an expanding demand for low-skilled migrant workers in both agricultural and nonagricultural sectors in the United States, particularly in the southwest; and by extensive "migration networks" connecting families throughout Mexico with low-skill U.S. jobs.

Characteristics of relatively settled migrants tend to look more like those of the U.S. population as a whole, even though differences between Mexican migrants and the total U.S. population, in many cases, remain significant. On average, compared with circular migrants, the settled-migrant population is more equally balanced between genders (55% male among all Mexico-born persons enumerated in the 1990 Census), slightly older (30 to 31 years of age) and better educated (yet with important differences across legal status and data source—35% of recent legal immigrants are high-school graduates and 15% are college graduates, compared with 26% and 6%, respectively, among recent entrants in the 1990 Census). Settled migrants have a slightly lower labor force participation rate, again varying by visa type and data source, with 85% of the men in the 1990 Census reporting labor force participation and 90% of recent legal immigrant men reporting U.S. employment, and are much less attached to agricultural jobs (4-13 percent employed in agriculture). On balance, relatively settled migrants have higher earnings and higher family incomes than circular migrants (among recent legal immigrants, U.S. annual earnings averaged $19,000 for men and $13,600 for women). However, family incomes are below the median for all U.S. households ($27,000 in the 1990 Census, compared with $38,000 for all U.S. households), and 27 percent lived below the poverty line in 1990 (the poverty rate for all U.S. households was 13%). Between 10 and 29 percent speak English well; among recent legal immigrants, 51% speak English at least "average or so-so."

Among Census-enumerated persons, those who report that they are naturalized (it is known that naturalization is seriously overstated in the Census) tend to look most like the total U.S. population with regard to their socio-demographic characteristics, labor-market experience, and incomes. Just over half (54%) are males, their average age (42 years) is higher than that of the all Americans (34 years), and 32 to 47% have a high school degree or more. More than 40% speak English well. Their average household incomes are $28,000 to $29,000, compared with $38,000 to $39,000 for all U.S. households. One in four naturalization-reporting Mexican migrants lived in households with income below the poverty line in 1990, a slightly lower percentage than for all Mexican migrants.

Both circular and settled migrant groups tend to be dominated by individuals with low levels of skills, relative both to the U.S. population as a whole and to the nonmigrant population in Mexico. However, they contain some highly educated individuals. For example, legal temporary residents (e.g, individuals with H-1 and J-1 visas) are drawn largely from the upper tiers of the Mexican skill ladder. (Legal temporary agricultural (H-2A) workers are the exception.) Some of these individuals are circular migrants. Others are relatively long-term U.S. residents. The number of highly skilled Mexican migrants is small relative both to the number of skilled people in the United States and to the total Mexico-to-U.S. migrant flow; however, it is significant relative to the skilled population in Mexico. Highly educated Mexico-born persons in the United States include Mexicans pursuing university degrees abroad. The subsequent migratory behavior of these individuals is of obvious importance to the two countries and deserving of future research.

There is a marked difference between the educational attainment of Mexico-born persons enumerated in the U.S. 1990 Census reporting entry in 1987 to 1990 and that of recent legal immigrants born in Mexico. As already noted, 35% of recent legal immigrants are high-school graduates compared to 25.7% of the Census-enumerated, and 14.5% of recent legal immigrants are college graduates compared to 6.3% of the Census-enumerated. Similarly, while 28% of the Census-enumerated have completed less than five years of schooling, the comparable figure among recent legal immigrants is 21%. At the upper end of the educational spectrum, while only 3% of the Census-enumerated have postgraduate schooling, 9% of recent legal immigrants do—exceeding the figure for native-born (7%).

Third, characteristics of Mexican migrants change over time. Some of these changes appear to be long term. For example, there is evidence that schooling levels of Mexican migrants are increasing over time, and migrants' origins and destinations are increasingly urban. Long-term changes in migrant characteristics partly reflect changes in the population at large in Mexico from which migrants are drawn, but they may also reflect changes in the selectivity of migration over time. Other changes are short-term, cyclical (i.e., related to recessions and expansions)

or discrete, resulting from exogenous shocks like droughts or floods. For example, one study found that characteristics of migrants change with U.S. business cycles, becoming more feminine, urban, and schooled in periods of economic expansion. Still other changes in migrant characteristics may be law- or policy-induced, for example, the large-scale legalization of migrants under IRCA. There are some indications that migration is becoming less selective and the characteristics of migrants more heterogeneous over time. This could be due to the operation of migration networks, buttressed by the family reunification provisions of U.S. immigration law, which reduce migration costs and risks.

The rest of this chapter is organized as follows: We begin in "The Populations of Interest" by discussing alternative definitions of the populations of interest, highlighting legal and behavioral definitions and noting the lack of easy correspondence between them. Next, in "Theoretical Frameworks, Policy Priorities, and Data" we briefly review the theoretical frameworks that undergird the studies and data from which our work draws. "Data Sources—Deficiences and Constraints" describes data sources, noting their strengths and weaknesses as well as their correspondence with different definitions of the populations of interest; we distinguish between origin-country and destination-country data sources. The heart of this chapter is "Measured Characteristics of Mexican Migrants in the United States," in which we present the characteristics of migrants. This chapter attempts to provide a concise statement of the population of interest, theoretical frameworks, data sources, and major findings. Details appear in the extensive set of research materials in Volume 2, pages 695 to 867, which are referred to frequently in this text.

The Populations of Interest

The first task is to define the populations of interest. What do we mean when we say, "Mexicans in the United States"?

The population whose characteristics are the focus of this study may be defined in several ways, and migrant characteristics may differ across differently-defined populations. The different definitions may be classified into two main kinds, legal and behavioral.

Legal Definitions

Pertinent identifiers include: country of citizenship (both at birth and currently); country of birth; country of last permanent residence; visa history in destination country. Measured characteristics may differ across populations defined by one or another legal criterion. For example, age, sex, and occupation may differ between Mexico-born and Mexico-nationals in the United States, or between

Mexico-born legal permanent residents of the United States and all Mexico-born in the United States.

It is obvious that in studying migrants and their descendants, a key classifying variable is citizenship status at birth. Accordingly, in Volume 2, pages 695 to 698. We review briefly the process of acquiring citizenship and/or nationality at birth in the two countries.

Behavioral Definitions

Pertinent migration types include: temporary migration in youth, long-term seasonal or "circular" migration, permanent residential migration, retiree migration. Moreover, populations may be defined by mother tongue rather than by nativity or citizenship. Again, measured characteristics may differ across migration streams that are differently defined. For example, naturalization patterns may differ between permanent prime-age migrants and retiree migrants.

Interrelation between Legal and Behavioral Definitions

There is no simple correspondence between legal and behavioral definitions, and, indeed, observed behavior may differ from the behavior presumed to be associated with particular legal statuses. For example, legal permanent resident aliens of the United States may behave like temporary or like long-term seasonal migrants, while legal nonimmigrants of the United States may behave like long-term permanent migrants, progressing through a long series of temporary visas.

Theoretical Frameworks, Policy Priorities, and Data

The data available to construct statistical profiles of migrants are the product of surveys designed for specific research and policy purposes. Theory and policy concerns determine the population(s) from which survey samples are drawn. Because of this, they also determine the migrant populations to which the findings of research using these data may be generalized. Theoretical frameworks and their implications for the selectivity of international labor migration and characteristics of Mexico-to-U.S. Migrants are the subject in Volume 2, pages 699 to 708. We briefly outline them here.

Migration research highlights five interrelated themes. First, migration decisions and migrants' activities in the destination country are shaped by an array of factors including the economic and legal conditions at both origin and destination, migrants' information about those conditions, the direct costs of moving, and characteristics

of migrants and their households. Second, migration is selective, reflecting differences in information and in the costs and benefits from migration. Third, migration networks play a key part, as they not only provide information but also affect the benefits and costs of moving. Fourth, migration is a dynamic process, unfolding over time and changing over time as the basic factors and the networks and the ensuing selectivities change over time. Fifth, much Mexico-to-U.S. migration is circular.

The village surveys from which we draw were guided by a household model in which family members allocate their labor time across destinations in such a way as to maximize the household's predicted or expected well-being (see Volume 2, pages 699 to 706). This view of migration may be viewed as a household version of the view enshrined in the Latin saying, *Ubi bene ibi patria*, "Where one is well off, there is one's country." However, it raises the possibility—indeed likelihood—of circular migration and of an on-going involvement of migrants in the affairs of their households of origin in Mexico. In order to raise income, insure against income risks, or gain access to scarce investment funds, households in Mexico participate in migration by sending one or more family members abroad. Often this migration is initially conceived by both household and migrant as temporary and for specific ends. However, there is a tendency for it to become more and more permanent as the migrants' economic and social (i.e., opportunity) costs of returning to Mexico increase and as migrants create new, often mixed-legal-status, households in the United States. This view of migration leads to a survey design focusing on "transnational households" in Mexico and gathering data on all family members associated with each selected household, regardless of whether they are in Mexico or the United States at the time of the survey. It sometimes requires combining village household surveys in Mexico with tracer surveys of migrants in the United States.

Well-being is shaped by many factors: social, economic, religious, political. Moreover, both the household's and potential migrant's future well-being—with versus without migration—are shaped by household and personal endowments and characteristics as well as by the ability to predict future well-being. The benefits from migration will differ across individuals, households, and countries, because of differences in migration costs, differences in the amount and type of benefits and differences in the availability of information. In this way, certain types of individuals, from certain types of households in Mexico, are selected into and out of international migration.

Circumstances shaping the costs and risks of migrating include distance and laws governing exit and entry. Important factors increasing benefits and mitigating costs and risks include migration networks, information, experience, and the availability of potential sponsors—relatives or employers.

The migration process is dynamic because many of the factors shift over time. For example, transportation costs may change, laws may change, patterns of rewards to skills may change. The evolution of economies in Mexico and the U.S. may alter the returns to particular skills (e.g., schooling in Mexico) or the mix of skills or worker characteristics demanded by employers of migrants (schooling, gender, etc.). Moreover, individuals and households may alter their own characteristics in order to enhance the probability of success in a migration strategy, investing in migration networks or schooling, developing fictive-kin (*compradazgo*) relations with village families who have relatives in the U.S., taking language courses, or gravitating to social clubs where potential sponsors may be found.

Viewed from a macro perspective, migration may be characterized as a set of localized migration streams, each stream possessing a history that can be traced to pioneer migrants and in which stages or phases can be discerned. Other things being the same, pioneer migrants tend to be more intensely positively selected than those who follow them. Because at any point in time different migration streams may be in different phases, migrant characteristics may differ across migration streams and hence across studies that target different streams. To complicate matters further, a large but unknown part of global migration flows is circular. Migrants often move back and forth across the Mexico-U.S. border as members of "transnational migrant circuits."

Most U.S. data sources (the U.S. Census of Population, CPS, and INS administrative records) are not designed to take into account the circularity of migration flows. The unit of analysis of the Census and CPS is dwellings in the United States, and the universe of individuals included in the Census consists of all who regularly reside in those dwellings. The Census lacks information on characteristics particularly relevant to the study of migration, such as legal status and visa type. It has other shortcomings for analyzing immigrant characteristics, as well, including undercounts of immigrants, particularly unauthorized ones (see the following "Data Sources—Deficiencies and Constraints").

In Mexico, government surveys including the ENADID have similar drawbacks, focusing on fixed households in Mexico and excluding many migrants in the United States who may actively participate in those households. They are guided by a definition of households based on co-residence or propinquity, a criterion that has been questioned in recent migration literature.

A theoretical framework of migration circularity underlies the three Colegio de la Frontera Norte (COLEF) surveys, whose focus is on measuring both northward and southward flows of migrants (see Volume 2, pages 702 tp 708). Circularity is understood as a social process involving interactions of people who orient their migration behavior toward an international labor market. It is a theoretical construct (not a descriptive category) that applies primarily to

international labor migration and not necessarily to all migrants. It is intended to depict the dynamics of social processes of interactions (including the subjective process of learning and deciding about whether or not to migrate internationally) taking place in the structure of an "imperfect labor market," in which wages are shaped by power asymmetries. In this market, labor demand is personified by employers of the host country who interact with a supply personified by migrant workers from a different country.

Circularity suggests a purposeful migratory movement related to the intersubjective meaning of work shared by the main actors (employers and migrant workers) in the complex structure of an international labor market. It is a dynamic result of the interplay between supply and demand in that labor market. This interplay is the "force" that makes people move back and forth across international boundaries. Migratory flows are conceived here as operationalizations of the processes of circularity of international migrations for purposes of empirical research. Migratory flows are understood as being associated in two dimensions, one of time and the other of space. The time dimension is operationalized by (a) the notion of a "migratory career," understood as the time lapsing from the first migration for the purpose of obtaining a job in the other country, to the time one drops out of the circulatory process on a permanent basis, and (b) the notion of a "segment" of that process, equivalent to what is referred to in the literature as "temporary migration."

From such an understanding of circularity comes the use of "sampling of mobile populations," adapted from bio-statistics, which focuses on patterns of empirically defined "migratory flows" (spacial dimension) and empirically defined timing of such flows (time dimension). The same scientific principles on which volumes of migratory species, including blood cells, are measured by biologists, are used in the COLEF studies to measure the socio-economic characteristics of Mexican migrants to the United States.

Similarly, a hallmark of the research design of the New Immigrant Survey is that new legal immigrants, once drawn randomly into the sample, will be followed over time wherever they reside, as will members of their families. Indeed, initial interviews with 28 sampled immigrants were conducted in a total of 20 countries, including Mexico.

Data Sources—Deficiencies and Constraints

Accurate and comprehensive description requires longitudinal information on probability samples of migrants, starting with preparations for the first visit and continuing to the end of life, and including family, educational, and occupational histories as well as visa history. Moreover, to understand the decision to migrate,

data on nonmigrants are also required. Finally, to understand the long-term consequences of migration, data on the descendants of migrants are also necessary.

The data needed to construct a conclusive and comprehensive portrait of migrants between Mexico and the United States do not exist. This report presents the characteristics of migrants as they appear in a variety of data sources. To the extent that these different data sources capture distinct populations—for example, INS administrative data on immigrants cover all persons granted permanent resident status in a given year, whereas U.S. census data cover all persons, of any visa status (adding nonimmigrants and undocumented migrants to legal immigrants) residing in the United States as of a given day and captured by Census enumerators—the portrait may differ by data source.

We distinguish between data based on samples drawn in Mexico and samples drawn in the United States. We shall refer to the former as Mexico data sources and to the latter as U.S. data sources. Notice that we do not say that the data are "collected" in the given country, for, although in most cases the data are collected in the same country in which the sample was drawn, in some research designs, as noted above, migrants are interviewed in both countries, as well as in other countries to which they may move.

Mexico Data Sources

We rely on five key Mexico data sources: the INEGI/ENADID, COLEF's EMIF and Zapata Canyon project surveys, and regional (mostly community) household surveys. Short descriptions are presented here; fuller detail is presented in Volume 2, pages 709 to 735.

INEGI/ENADID

The National Survey of Demographic Indicators (Encuesta Nacional de Indicadores Demográficos, or ENADID), carried out in 1992, provides a basis both for estimating selected migrant characteristics and for comparing characteristics of migrants with those of nonmigrants.[2] It offers advantages, particularly with regard to sample design and methodology, over its precursor, the 1978-79 National Survey of Emigration to the Northern Border and to the United States (Encuesta Nacional de Emigración a la Frontera Norte del País y a los Estados Unidos, or ENEFNEU) by the Centro Nacional de Información y Estadísticas del Trabajo of the Mexican Secretaría del Trabajo y Previsión Social (CENIET, 1978; also see Ranney and Kossoudji, 1983). The ENADID survey's coverage includes both return migrants and individuals who were in the U.S. at the time of the survey. Return migrants responded directly to questions about their migration activities. Information on

sociodemographic characteristics of migrants who were in the U.S. at the time of the survey was provided by other members of the migrants' families in Mexico. Information provided by return migrants includes migration histories, making it possible to analyze changes in some migrant characteristics and in the migration environment over time. The survey also provides information on the domestic units from which migrants originate in Mexico; households in Mexico are the units of analysis for the survey.

The ENADID survey has three chief drawbacks. First, because it relies upon family members in Mexico to report on migrants who are in the U.S. at the time of the survey, information on migrants is limited. The ENADID survey probably is a good source of information on basic sociodemographic information of migrants, but not on specifics of migrants' labor-market experience in the United States, and it misses migrants not considered to be members of households in the sample. Although in theory its universe includes migrants in the United States, in practice it appears that few individuals who were in the United States at the time of the survey were enumerated; coverage included only individuals who had migrated to the United States in the previous five years; and, for those who were enumerated, data were gathered only on a few sociodemographic characteristics. Second, the survey misses entire domestic units that have migrated. If characteristics of individuals in these units differ from characteristics of individuals whose families remain in Mexico, estimates from the ENADID survey will be biased. It is possible, for example, that families with few assets and income possibilities in Mexico are more likely to migrate as complete family units than families having a stronger financial footing in Mexico. The third major drawback of the ENADID survey is that, while rich in demographic information, it lacks the detailed economic information, available in some community surveys (see below), to test for the selectivity of migration or migration impacts. For example, family assets (e.g., landholdings), income, and remittances from internal migrants and Mexico-to-U.S. migrants are not available.

EMIF and the Zapata Canyon Project

The Survey of Migration at the Northern Border (Encuesta sobre Migración en la Frontera Norte, or EMIF), attempts to capture the characteristics of distinct flows of Mexican labor migrants. The theory and methodology for this survey was developed by a team at the Colegio de la Frontera Norte (COLEF) headed by Jorge Bustamante, in collaboration with Jorge Santibáñez y Rodolfo Corona. Its objective is to study the circularity of migration using a method of sampling mobile populations. Labor migrants are identified on the basis of their migratory behavior, that is, their displacement from a city or community of origin to another city or

community for the purpose of working. This is a continuous survey, making it possible to capture variations in total migration flows and in the participation of different population subgroups in migration across the Mexico-U.S. border at different times of the year. Individuals leaving Mexico to work in the U.S. as well as return migrants are surveyed at carefully selected points at or near the border. The survey has been carried out in two stages, the first, from 1993 to 1994, and the second, from 1994 to 1995.[3] The chief drawback of the EMIF is that it focuses on labor migration; non-labor migrants are not enumerated. EMIF data on circular migrants are available for 1993-94 and 1994-95. Unless otherwise noted, findings reported here are from the 1993-94 data set.

While the ENADID survey includes all types of migrants, independent of duration or purpose for migrating to the U.S., the EMIF provides information only on individuals who have worked in the United States or who reveal an interest in migrating to the U.S. for purposes of working. The two surveys also have very different methodologies. The ENADID survey targets individuals at their place of normal residence in Mexico. The EMIF focuses on migrant flows, that is, persons in transit to, or returning from, the U.S. EMIF makes it possible to estimate the volume of migrant flows. In this respect, it is unique.

The precursor to EMIF was the Zapata Canyon project, also conducted by COLEF. During several decades, the largest south-north flow of undocumented migrants across the border was in the Zapata Canyon area, a plateau in U.S. territory with access from the Colonia Libertad in Tijuana. Groups of undocumented workers would gather here, waiting to cross the border under cover of darkness. Researchers systematically observed undocumented migrant flows and recorded them using photographic techniques, here as well as at several other points along the Mexico-U.S. border. After several pilot tests, in September 1987 El Colef researchers began surveying randomly chosen undocumented migrants about to cross the border, using quick interviews based on small questionnaires (3 minutes) in the towns of Tijuana, Mexicali, Ciudad Juárez, Nuevo Laredo and Matamoros, on Fridays, Saturdays and Sundays of every week, from September 1987 to the present. Some findings from this project are presented below. This survey's main drawback is also its main strength: It includes only undocumented migrants, providing valuable data on this difficult-to-survey, clandestine population. It also offers a time-series view not available from most other data sources.

Household and Community Surveys in Mexico

Formal household surveys, usually encompassing one or more small geographic areas, have been the basis for most recent research on characteristics of Mexico-to-U.S. migrants and their evolution over time. Most of these surveys center on villages

or towns in rural Mexico. They have been carried out by researchers in a range of social science disciplines, including sociology, anthropology, and economics. Whereas geographic coverage and sample size are the strengths of the nationally representative data sets discussed above, depth and detail are the great advantage of community survey data.

Household surveys offer potentially the most reliable basis for estimating characteristics of Mexico-to-U.S. migrants from the places covered by these surveys. A good survey design involves random sampling of village households (typically, dwellings) and a survey instrument that gathers information on all close relatives of those living in the household—whether currently in Mexico or in the United States. Even if an entire family moves to the United States (which is rare), data from other households (e.g., containing parents or siblings) may be used to ascertain a person's characteristics if comprehensive lists of family members are assembled as part of the survey. Data from a well-designed village survey should:

- Make it possible to construct a detailed portrait of the characteristics of migrants and of the households and communities from which they come
- Provide a basis to compare those who migrate to the United States with those who do not (the latter include nonmigrants and internal migrants)
- Provide a means to correct for sample selection bias when estimating, for example, migrant earnings, remittances, and net income contributions to village household incomes.

Surveys of small numbers of households (50-100 households per community are typical of community surveys in Mexico) are relatively easy to reproduce. Because of this, community household surveys offer some of the most reliable—and in some cases, the only—basis for analyzing changes in migrant characteristics over time.

The major disadvantage of using household surveys to estimate migrant characteristics is that it is not obvious how to generalize from surveys of small places (e.g., villages, rural towns or urban neighborhoods) to the migrant population at large. The best bet for individual researchers at this time is to replicate surveys in many places situated in diverse settings, and to compare findings across surveys. This approach has been adopted by several sociological and economic researchers in Mexico. Unfortunately, most of their research has focused on states that traditionally have sent large numbers of migrants to the United States. Because of this, the communities canvassed by these surveys tend to have a high prevalence of migration. Estimates of migrant characteristics from these data may represent characteristics of migrants from "old" migrant-sending areas (e.g., Michoacán) better than from "new" ones (e.g., Oaxaca) if the types of individuals who are

selected into migration change over time. Community survey questionnaires reflect specific research interests of those who carry out the surveys. The breadth and detail of data vary from survey to survey.

The alternative to replicating surveys of places in Mexico is to carry out more geographically expansive and coordinated surveys (e.g., the ENADID study) or to conduct surveys of migrants at points of entry and exit between the two countries (EMIF). Not only do these surveys sample different subpopulations of migrants, but they also illustrate the difficulties inherent in obtaining a very high level of detail on a large number of variables in surveys covering very large geographic areas and in which expanding the survey questionnaire comes at a high cost (ENADID) or simply is impractical for a universe in transit (EMIF). As a result, to date there is nothing approaching a national Mexican data set from which to reliably estimate the array of Mexico-to-U.S. migrant characteristics in which we are interested, analyze the selectivity of Mexico-to-U.S. migration, or assess impacts in Mexico or the United States. The level of detail required to address many of the questions with which our research is concerned can be found only in data sets covering a few villages or towns.

The two major community-focused surveys we utilize are from the Mexican Migration Project (Durand and Massey) and the Michoacán Project (Fletcher, Orlove, and Taylor). The Mexican Migration Project provides cross-sectional data from random samples of households surveyed in 1982-83 and 1987-91 in 19 communities in the Mexican states of Jalisco, Michoacán, Guanajuato, and Nayarit, areas that have traditionally sent large numbers of migrants to the United States. Within each community, 100-200 households were randomly selected and interviewed, resulting in a total sample size of 3,400 households across 19 communities. Detailed socio-demographic data were gathered, together with migration life histories.

The Michoacán project provides time-series data on 30 households from each of two Michoacán communities over three different years (1982, 1988, and 1992), together with cross-sectional data on 200 households in four communities (1,820 individuals) in 1992. The focus of this survey was more economic (and somewhat less demographic and qualitative) than the Durand-Massey survey: The survey provides detailed data on incomes from all sources, the allocation of family time across all income-producing activities, including migration, as well as sociodemographic characteristics of all family members (whether present or not at the time of the survey) and household assets. The Mexico Migration Project and Michoacán survey data sets have been the source of information for most of the statistical studies of Mexico-to-U.S. migration and its impacts in rural Mexico that have appeared in major economic, sociological, and demographic journals over the past decade.

U.S. Data Sources

We rely on four main U.S.-side data sources: (i) the decennial Censuses and the Current Population Surveys, including microdata as well as published tabulations (such as the historical time series published in *Historical Statistics of the United States*); (ii) information on legal immigrants, including official government information (microdata compiled by the U.S. Immigration and Naturalization Service (INS), tabulations published by the INS in its *Annual Report* (published 1943 to 1977) and the successor *Statistical Yearbook* (published since 1978), and tabulations published by the U.S. Department of State in its annual *Report of the Visa Office*), a special microdata sample assembled from INS data by the General Accounting Office (GAO), and preliminary data from the New Immigrant Survey; (iii) farmworker survey data, and (iv) information from the COLEF/USC Los Angeles Project. Brief summaries are presented here; fuller detail is provided in Volume 2, pages 735 to 745.

Foreign-Born in the Decennial Censuses and the Current Population Surveys of the United States

The U.S. decennial censuses and the Current Population Surveys (CPS) are among the major sources of data used by researchers to study the characteristics of migrants. Public-use microdata files are available for the Censuses of 1900, 1910, and 1940 through 1990.

Data drawn from the decennial Censuses and the Current Population Surveys of the United States share several strengths and weaknesses. The major strength is the richness of information on the foreign-born, including socioeconomic and demographic information such as schooling, labor force participation, occupation, earnings, and knowledge of English. Additionally, the censuses have large sample size for the migration-relevant characteristics, enabling examination of relatively small subgroups. The principal shortcomings of these data are their cross-sectional nature and the absence of information on the migrant's legal status. Cross-sectional data are vulnerable to biases arising from emigration selectivity as well as from the confounding of cohort and experience effects. With respect to visa status, the only information available on the foreign-born is whether they are naturalized; thus, we cannot distinguish between the occupational and other behavior of immigrants and that of legal nonimmigrants (with and without permission to work) and undocumented (or deportable) migrants. Moreover, Census information on naturalization is problematic. The Census also suffers from problems related to undercounts of immigrants, raising questions about differences in characteristics between immigrants enumerated in the Census and CPS and those missed.

Legal Immigrant Samples Based on Administrative Records of the INS

Samples based on administrative records of the INS constitute the major source of information about legal immigrants. These data are of two main types: (i) administrative records covering new legal immigrants and new naturalized citizens; and (ii) surveys of samples drawn from INS records.

INS Administrative Data.

Data collected by the INS as part of its administrative work provide an important complement to census data. The strengths and weaknesses of INS data are also complementary to those of census data. The principal strength is the rich detail on legal status, coupled with information on country of birth, country of last residence, country of chargeability (for immigrants holding numerically restricted visas), and country of citizenship. The principal weakness is the absence of information on schooling, earnings, and other pertinent socioeconomic variables.

In this report we utilize microdata from three annual cohorts of new permanent resident aliens (FY 1977, 1982, and 1994), two of which (FY 1977 and 1982) are matched to subsequent naturalization data, and from a data set compiled by the General Accounting Office which provides information on the sponsors of new immigrants admitted in FY 1985 as the spouses, parents, and children of U.S. citizens. As well, we utilize time series from data published in the INS annual reports.

INS data on legal immigrants include, for the subset who is adjusting status from a nonimmigrant status, the type of nonimmigrant visa and the year of its inception. As a supplement to this information, it would be useful to have information about the larger population of legal temporary residents. At any given time, an unknown number of Mexico-born persons are in the United States as temporary visitors. The wide range of available visa types covers a variety of permissible durations of stay and includes both visas that proscribe employment and visas for the express purpose of employment. It would be useful to have a time series of the number of persons holding such visas. Unfortunately, INS data record arrivals rather than persons, and "nonimmigrants in several classes of admission, especially students, intracompany transferees, and visitors for business, often enter (and leave) many times in any given year" (INS 1994 Statistical Yearbook, p. 101). Thus, for example, while the 1994 INS Statistical Yearbook reports 14,773 arrivals of Mexico-born persons holding student visas, that number is an upper bound, and the true but unknown number may be considerably smaller.

Surveys of Samples Based on INS Administrative Data

The principal weakness of INS administrative data—the lack of information on schooling, earnings, and other variables—can be overcome by collecting that information from individuals randomly selected from the administrative data. Such a design loses none of the strengths of designs based on INS administrative record, overcomes the deficiencies, and, when embedded in a longitudinal data collection framework, overcomes as well the problems associated with cross-sectional data, such as emigration selectivity and confounding of cohort and experience effects.

In this report we draw on a special study carried out by the GAO on the immediate-relative immigrants of FY 1985 and on two main INS-based sample surveys. These are the special two-wave survey of the IRCA legalized population, LPS-1 and LPS-2, and the baseline interview data from the New Immigrant Survey Pilot Study.

GAO Study

As was noted above, INS data do not include information on an immigrant's sponsor. The General Accounting Office assembled a microdata set containing information on the U.S. citizen sponsors of a probability sample of immediate relatives who became permanent resident aliens in FY 1985. The GAO data include information on whether the sponsor was him/herself an immigrant and on his/her country of birth. If the sponsor was an immigrant, then information is also provided on the date of admission to immigrant status and the date of naturalization. The data thus make it possible to distinguish not only between birth-citizens and naturalized citizens but also, within birth-citizens, between those born in the United States and those born abroad to U.S. citizen parents.

Legalized Population Surveys

The Legalized Population Surveys, LPS-1 and LPS-2, represent two rounds of a longitudinal survey of a sample of persons legalized under Section 245A of the 1986 Immigration Reform and Control Act. These are persons who had lived in the United States continuously since January 1, 1982, had applied to the INS for legalization, and had been granted legalization in the first phase of the IRCA program (i.e., had been granted legal temporary resident status). During the first round, carried out in February to June of 1989, a total of 6,193 persons were interviewed. The second round selected for interview a subset of the initial interviewees; a requirement for participation in the second round was successful admission to legal permanent resident status. Thus, the population covered by LPS data represent a

subset of unauthorized migrants who were in the United States in 1989. It is not necessarily representative of the entire unauthorized migrant population either before or after 1982. Nevertheless, the Mexican subset of the LPS sample provides an important complement to other data sources to estimate characteristics of Mexican migrants, and it includes some variables (e.g., on remittance behavior) not available in other data sets.

NIS Pilot Study

To improve the data base on immigrants, a program of comprehensive, multicohort, longitudinal surveys of new legal immigrants to the United States based on probability samples of INS records was recently developed. This program—the New Immigrant Survey—is designed to monitor changes across cohorts, with new samples drawn periodically, and to monitor adaptation over time, interviewing sample members at regular intervals over the life cycle and also obtaining information about and from their children. To test the design, and in particular to assess the cost-effectiveness of alternative methods of locating and tracking immigrants—with the aim of maximizing both initial and longitudinal response rates—a Pilot Study is being carried out. The Pilot Study includes a baseline interview and follow-up interviews over the course of a year. The sample is a probability sample drawn from among the set of persons who became new permanent resident aliens during July and August of 1996. In this report we draw on preliminary results from the baseline interview of the Pilot Study, which collected information on schooling, English language skill, labor force participation, and earnings both in the United States and abroad.

Farmworker Survey Data

Almost two thirds of all seasonal agricultural service (SAS) workers are foreign born, and over two-thirds are of Hispanic origin. In California, 92 percent of SAS workers are foreign born, and 80 percent are from Mexico (US Department of Labor, 1993). Because of this, farmworker surveys are an important source of data on Mexican migrants, especially undocumented migrants. Year of entry in U.S. Census data has been used as a proxy for legal status in some research on Mexican migrant impacts and labor-market performance in the U.S. (e.g., Bean, Lowell and Taylor, 1988). However, direct estimates of characteristics of unauthorized Mexican migrants are complicated by a lack of data. Besides INS border apprehension data, U.S. data to estimate characteristics of undocumented migrants in the United States have come primarily from farmworker surveys. Because farmworker surveys sample both legal and undocumented migrants and attempt to ascertain the legal status of

migrants, they provide a potentially reliable source of data to estimate the characteristics and labor-market performance of these two groups and a basis for comparison with native workers (Mines and Martin, 1986; Taylor and Espenshade, 1987; Taylor, 1992a).

The UC-EDD Survey of California Farmworkers was carried out by the University of California, Davis (UC) and the State of California Employment Development Department (EDD) in August 1983. The usable sample includes 554 male farmworkers in 37 counties; workers in all crops and production-related activities were interviewed in each survey area. The survey was designed to obtain as representative a statewide sample of farmworkers as possible, given the well-documented difficulties inherent in studying this population. The data provide information on farmworker human capital and other sociodemographic characteristics, including immigration status and country of origin; on the type of work and commodity in which farmworkers were employed at the time of the interview; and on farmworker earnings. Just over 80 percent of all farmworkers in the survey were Mexican-born, and 29 percent were undocumented.

The National Agricultural Workers Survey (NAWS) was carried out in response to the legislative requirement under IRCA that the Secretaries of Agriculture and Labor determine annually if there is a shortage of Seasonal Agricultural Service (SAS) workers. The NAWS collects comprehensive job history information on SAS workers to estimate fluctuations in the labor supply. It also gathers sociodemographic and earnings data, similar in most respects to the UC-EDD survey. Only farm workers employed in SAS labor are interviewed for the NAWS. More than 2,000 such workers were interviewed in fiscal year 1990.

The main concerns surrounding the research use of farmworker survey data have concentrated on difficulties in sampling a mobile and in many cases illegal population of farmworkers. This raises questions especially about the self-selectivity of interviewees and reliability of information provided by respondents about their immigration status. If undocumented migrants misrepresent themselves as legal immigrants in these surveys, this will tend to reduce estimated differences between legal and undocumented migrants in terms of socioeconomic characteristics and labor market impacts and performance. Despite this limitation, studies using farmworker survey data reveal significant differences between the two Mexican migrant groups.

The second major limitation of farmworker survey data is that they are sector specific. Although they may provide a reliable means to sketch a statistical portrait of Mexican migrants in agricultural labor markets, they are not generalizable to the Mexican migrant population outside of agriculture, because characteristics and labor market performance of Mexican migrants selected into farm work differ from those of Mexican migrants in other sectors. This limitation is compensated for partly by

the fact that agriculture serves as a traditional port of entry for many new Mexican migrants, and as such, it offers a window into changing characteristics of what probably is the most disadvantaged segment of the Mexican migrant population in the U.S. Although there are other immigrant- and unauthorized-migrant-intensive sectors in the U.S., no data collection effort in those sectors approaches the scale and rigor of farmworker surveys.

A third unfortunate limitation is that the most recent comprehensive data on Mexican immigrant farmworkers in the U.S., the NAWS, have not been made available for public use—all studies using these data have been carried out either in-house, at the Department of Labor, or else by a small group of non-DOL researchers authorized to use the data for research purposes. The DOL would not make NAWS data available to us for this project. Because of this, most of our information on characteristics of Mexican-migrant farmworkers comes from the 1985 UC-EDD Farmworker survey.

The Los Angeles Survey (COLEF)

The Mexican Migrant Survey was undertaken jointly by COLEF and a team of researchers from the University of Southern California (USC). It's design is based on the same methodology of "sampling of mobile populations" followed in EMIF. Ethnographic field work helped identify four kinds of places through which internal streams of migrants usually flow within the city of Los Angeles: a) shopping centers within the Los Angeles SMSA (Standard Metropolitan Statistical Area) where the highest percentages of people of Mexican origin are found, b) soccer fields, c) food wagons near work centers where Mexican migrant workers are concentrated, and d) "quadrants," places where migrant workers gather, generally at specified street corners, seeking day work. Interviewers were sent to a randomly selected sample of places and food wagons, where they surveyed randomly chosen migrants.

Towards a Typology of Data Sources

As the foregoing description of data sources suggests, the data sources we use cover many different subsets of Mexico-born persons in the United States. Table 1 provides a representation of the types of migrants, by legal status, that can be identified in our data sources. The data sources are grouped by the country where the sample was drawn. The table identifies the major types of foreign-born persons—naturalized citizens, legal immigrants, legal nonimmigrants with permission to work, legal nonimmigrants without permission to work, and deportable migrants (which includes legal nonimmigrants who violate the terms

Table 2
Characteristics of U.S.-born Immigrant and Unauthorized Immigrant and Farm Workers (1985) UC-EDD Survey Data

Source: Analysis of UC-EDD Survey Data. The survey is described in detail in Mines and Martin (1986).

of their visa as well as entrants without inspection). As shown, and as discussed earlier, the only group of foreign-born that can be distinguished in census and CPS data is that of naturalized citizens; all others, including legal immigrants, legal nonimmigrants, etc., are lumped together in one group.

An alternative way to categorize data sources is by migration-behavior criteria, i.e., data sources representing relatively settled Mexican migrant populations and households and those representing less permanently settled populations of circular migrants. Data sets specifically designed to gather information on flows of circular migrants include the EMIF, Zapata Canyon and Los Angeles projects. The ENADID data focus primarily on return migrants; thus, they would tend to fall into this group, as well. Data sources that could be considered as largely focusing on relatively settled migrant populations and households include the United States Census and CPS, INS administrative data, the LPS, and data from community surveys in Mexico. These data sources may be interpreted as providing information on the stock of migrants in the United States more than on the flow of migrants across the border. Of course, relatively settled migrants also emigrate.

Although findings on migrant destinations vary widely from one data source to another, they are often similar within these two groups of data sets. We therefore refer to these behavioral categories when presenting our findings on migrant characteristics.

The data sources not only fall along a continuum from representing more settled to less settled, circular migrant populations; they also cover different points in time. Surveys focusing on migrant flows and surveys focusing on migrant stocks yield different findings at different points in time. We emphasize this time dimension of surveys, particularly when it may offer insights into how the characteristics of migrant stocks or flows change over time.

In this chapter we follow the convention of using the terms “foreign-born” and “migrant” as generic terms, that is, encompassing all Mexico-born persons in the United States. We use the term “immigrant” to refer to legal immigrants (i.e., permanent resident aliens—”green card” holders) and “nonimmigrant” to refer to legal nonimmigrants. Persons who do not migrate are called “nonmigrants.”

Measured Characteristics of Mexican Migrants in the United States

Mexico-to-U.S. migrants have tended to be selected from the middle-to-lower ranges of the socioeconomic hierarchy; from rural areas and agricultural jobs in Mexico; and for low-skill jobs in the United States. (For an historical overview of Mexican-migrant characteristics from Mexican authors, see Volume 2, pages 769 to 778) This selection process originated at the start of this century with the

recruitment of low-skilled Mexican workers by U.S. employers for seasonal jobs, mostly in agriculture. It has been facilitated by the long and historically porous border between Mexico and the United States, which puts U.S. labor markets within reach of individuals with limited financial resources, by an expanding demand for low-skilled migrant workers in both agricultural and nonagricultural sectors in the United States, particularly in the southwest; by direct contracting, and by extensive migration networks connecting families throughout Mexico with low-skill U.S. jobs. This selectivity is evident in the youthfulness and low skill levels of Mexican migrants, relative both to other migrant groups and to the U.S. population at large.

In this section, we present a summary of migrant characteristics; fuller detail is provided in the tables in Volume 2, pages 747-778.

Migration Patterns: Origins in Mexico and Destinations in the United States

Places of Origin in Mexico

Although migrants originate from throughout Mexico, the west-central region (Michoacán, Guanajuato and Jalisco) traditionally has had the highest levels of out migration.[4] Gamio found that, in 1926, 54.3 percent of all monetary remittances from the United States were directed to this zone. This indicator of migrant origins coincides with findings from other researchers, although the importance of this region appears to have diminished over time.

Virtually all of the data available to identify migrants' places of origin in Mexico are from surveys that we regard as representing relatively unsettled, circular migrants (ENADID, EMIF, and Zapata Canyon Project). Sources of data on relatively settled migrant populations either do not offer information on migrant origins within Mexico (U.S. Census and INS data) or else represent only selected places of migrant origins (community surveys in Mexico).

Data from the 1992 ENADID indicate that the west-central zone accounted for only 36.9% of all migrants who had resided or worked in the U.S. and 38.9% of those who had lived in the U.S. over the previous five years. The traditional migrant-sending states had been joined by Zacatecas, Durango, Mexico City, Chihuahua, Tamaulipas, Guerrero, and the State of Mexico, in that order, as the most important sources of Mexican migrants for the United States. Together, these ten states accounted for over 70 percent of the migrant total. The share of migrants in the total populations of migrant-sending states varied. It was highest in Zacatecas, where 9.7 percent of the population surveyed in ENADID had lived or worked in the United States. It was 8.3 percent in Durango, 8.2 percent in Michoacán, and 6.5 percent in Jalisco. In contrast, the share was only 0.9 percent in Mexico City and 1 percent in the State of Mexico.

ENADID data reveal that shares of recent migrants (those reporting living in the U.S. between 1987 and 1992), were highest for individuals born in Michoacán (3.05%), Durango (2.85%), Zacatecas (2.7%) and Colima (2.5%). At the other extreme, the smallest shares of recent migrants in migrant-sending states were in Tabasco (0.01 percent), Quintana Roo (0.04%), Chiapas (0.07%), and Campeche (0.08%).

A broader picture of migrant sources can be constructed by dividing Mexico into six regions, based on the geographic distribution of migrant birthplaces, using ENADID data:

I. The regions of greatest out-migration, with 37.8% of all migrants, composed of Guanajuato, Michoacán, Jalisco and Colima.

II. The northern-border states—Baja California including Baja California Sur, Sonora, Chihuahua, Coahuila, Nuevo León and Tamaulipas—which account for 20.8% of all migrants.

III. The six states located in between regions I and II—Sinaloa, Durango, Nayarit, Zacatecas, San Luis Potosí and Aguascalientes—with 21.5% of the total.

IV. The five interior states in and surrounding the Valley of México—the Federal District, State of México, Querétaro, Hidalgo and Tlaxcala—with 9.2% of all migrants.

V. Oaxaca, Guerrero, Puebla and Morelos, with a combined share of 8.2%.

VI. The six southwestern states—Veracruz, Tabasco, Chiapas, Campeche, Yucatán and Quintana Roo—accounting for only 2.4% of the migrant total.

If one considers only recent migration, the weight of Region I increases to 39.9%.

The EMIF data indicate that the importance of Region I in circular migration flows is smaller, however. Region I accounts for 37.4 percent of migrants returning from the United States and 27.7% of deported migrants in the EMIF data.

Findings from EMIF data on migrant origins for 1993-94 reported here are based on place of birth, while those for 1994-95 are based on place of residence prior to migration, not birthplace. ENADID data on recent migrants show flows from region III exceeding those from region II (19.2 percent, compared with 16.8 percent). Among deported migrants, however, region II leads region III (22% versus 20.4%). In the EMIF data on migrants returning from the United States, like in the ENADID data set, the share of those from region IV is larger than the share from Region V (11.9 percent, versus 9.7 percent). However, in flows of those en route to the United States and in the deported-migrant sample (EMIF), the Region-V share

is greater than the Region-IV share (e.g., for deported migrants, the shares are 16.3 percent for Region V and 10.2 percent for Region IV), despite Region V's greater distance from the border. In the most recent EMIF data, the Region-V states of Guerrero and Oaxaca rank seventh and eighth, respectively, as sources (places of prior residence) of north-bound migrants, but they do not rank in the top ten states for returning migrants.

Many people migrate internally before migrating to the United States, as evidenced by comparing places of origin defined by birth with those defined by residence prior to migration. When one uses the residence instead of the birthplace criterion, the weights of Regions I, III, and V decrease, while those of Regions II and IV (the border and the Valley of Mexico) increase substantially (EMIF). The share of migrants originating from Region I decreases from 37.8 to 33.8 percent, and the share from Region III declines from 21.5 to 16.1 percent. Meanwhile, the share increases from 20.8 to 29.1 percent in Region II and from 9.2 to 12 percent in Region IV.

The Zapata Canyon project gathered data on the state in which migrants lived prior to migrating (as opposed to birthplace). They reveal that, on average between 1988 and 1996, Michoacán and Jalisco were the largest suppliers of undocumented migrants in the Tijuana sector, where far and away the largest flows of migrants crossed the border—they represented 14 and 12 percent, respectively, of undocumented migrants crossing at this point. However, these two states generally do not dominate at the other border-crossing areas targeted by the survey. They tie for second (with 9.4 percent) behind Sinaloa (13.8 percent) in Mexicali, but they do not figure prominently farther east, in Ciudad Juarez, Nuevo Laredo, or Matamoros. Moreover, the data reveal that Mexico City surpassed both these regions in 1995 as the principal source of undocumented migrants at the Tijuana crossing. This is probably because of the use of residence prior to migration rather than birth place to determine migrant origins in this survey. Migration from Oaxaca and Guerrero increased during the period covered by the Zapata Canyon project. Other states in the Southeast of Mexico with Indian populations as poor as, or poorer than, the Mixteco and Zapoteco of Oaxaca and Guerrero show no significant migration to the United States. One of the most striking features of the Zapata Canyon findings is the diversity of Mexican migrants' origins, particularly at the westernmost crossings, but also the shift towards urban origins and the increasing importance of Oaxaca and Guerrero as migrant sources between 1988 and 1996.

Rural Versus Urban Origins

Migrants traditionally originated from rural areas in Mexico[5]. Although this trend has weakened, a slightly larger share of migrants continues to originate from

rural areas. ENADID data put the rural share at 59.1% for individuals living in the United States in the previous five years. EMIF data place the rural share at 61.7 percent. Only among deported migrants is the urban-origin share higher than the rural share (58.7%).[6]

The classification of migrant origins as rural versus urban is sensitive to whether birthplace or residence is used as the classifier, because many internal migrants shift their place of residence from a rural birthplace to an urban area, and some of these individuals subsequently migrate to the United States. Using residence as the criterion, the urban share in ENADID rises from 40.7 percent to 47.4 percent.

ENADID data indicate marked differences in rural versus urban origins across regions. While the Valley of Mexico and border regions have small shares of rural migrants (32.1 percent and 38 percent, respectively), in other regions the rural share is over 60 percent, reaching 73.1 percent in the six Region-III states.

Destinations in the United States

U.S. destinations of Mexican migrants are available both from surveys of circular migrants and from data on relatively settled migrant populations.

For historical, geographic, and labor-market reasons, Texas was the leading destination for Mexican migrants prior to the 1920s. Gamio (1930), drawing from U.S. Census data, estimated the share of Mexican migrants going to Texas at 68.7%, followed by Arizona (13.7%), California (7.8%) and New Mexico (6.4%). The 1920 Census showed Texas' share falling to 52.5%, while California's share more than doubled (to 18.8%), exceeding Arizona (12.8%). New Mexico's share fell to 4.2%. Meanwhile, Colorado became a migrant destination, with 2.3% of the total. Based on money orders sent to Mexico in 1926-1927, California took first place (36.2%), followed by Texas (15.7%), Illinois (12.2), Indiana (5.1%), Arizona (4.8%), Michigan (3.4%), Pennsylvania (1.8%) and New Mexico (1.4%).[7] The geographic distribution of migrants suggested a high proportion employed in agriculture, in towns and small cities, with a smaller proportion working in industrial jobs in cities like Chicago, Los Angeles, San Antonio, and the outskirts of Pittsburgh (Gamio, 1930). Overall, there was a significant dispersion of migrants in this early period. Nevertheless, most migrants appear to have returned to Mexico—some during the recession years of 1921-22 and others during the Great Depression following 1929 (Fonseca: 1986).

During the Bracero Program, Mexican migrants fanned out across a broad geographic area: Texas, California, Arizona, Indiana, Delaware, Michigan, Arkansas, Montana and Washington, among other states. Nevertheless, the importance of the southwest, particularly California, continued (Fonseca, 1986; Trigueros, 1994;

Alarcón and de la Peña, 1989). Following the end of the Bracero Program, migrant destinations remained diverse, but migrants became increasingly concentrated in California and Texas. In the 1978 ENEFNEU survey, California was the premier destination (47.3%), followed, in a distant second, by Texas (27.4%) and then Illinois (7.4%), New Mexico (2.7%) and Arizona (2%).

The predominance of California and Texas has continued, both for relatively settled migrants and for circular migrants. INS data indicate that the top two destinations for the Mexico-born men and women of the 1977, 1982, and 1994 legal-immigrant cohorts were California and Texas. Illinois was the third choice in all three years. Secondary but substantial contingents chose Arizona, New Mexico, and the state of Washington.

The EMIF found that, among circular migrants crossing the border from the south with prior migration experience, 42.3 headed for California, followed by Texas at 30 percent, New Mexico (4.4 percent), Arizona (4.2 percent) and Florida (3.1 percent).

Most deported migrants (81.9%) were in the United States only for a few hours; thus, we have information on destinations for only 18.1% of these cases. Nevertheless, their destinations are consistent with those from other data sources. California is first with 44% of deported migrants, followed by Texas (31.9) and Arizona (12.7%).

The findings presented above—especially from data on deported migrants—may be biased in favor of the U.S. border states; apprehensions are less common in states farther from the border than in the border area, where INS surveillance is highest. Because of this, the U.S. destinations of migrants—including circular migrants—may be more dispersed than indicated above.

Among cities, according to the EMIF, Los Angeles is the single most important destination for circular migrants, claiming a share between 6.2 and 7.9 percent, depending on the flow. It is followed by San Antonio, the Texas Valley, Houston, Dallas-Fort Worth and El Paso, with shares of 4.2 to 5.4%; Fresno, California (3 to 4.3 percent); and Phoenix (2.9 to 7.3%).

The importance of California and Texas as destinations for circular migrants is widespread across regions of origin in Mexico, but it varies depending on migration traditions and family migration networks. In the EMIF data, among migrants originating from the south and among deported migrants, California is the primary destination for regions I, III, IV and V and is most important in regions I and V (for region V, California draws 77% of those who migrate and 76.2% of deported migrants). Texas ranks first as a destination for migrants from the border region in all three flows enumerated by EMIF (south-north, north-south and deported migrants). Texas also ranks first for regions III and IV, if measured by return (north-south) flows (60.7 percent in the latter region). The dispersion of migrants across

U.S. states is greatest for the Valley of México region. The concentration of migrants in a small number of states is greatest for migrants originating in regions I and V.

Micro-regional studies in the state of Michoacán indicate that communities tend to specialize in terms of migrant destinations. Migrants from Napízaro and Puácuaro, two communities in the Pátzcuaro region, go almost entirely to the San Fernando Valley north of Los Angeles. Migrants from Chavinda, a small community near Zamora, migrate to the San Joaquin Valley, Salinas Valley, the San Francisco Bay area, and a barrio in Central Los Angeles (Alarcón, 1986:345). For migrants from Jaripo, the poles of attraction are Los Angeles, Oxnard, San José, and San Joaquín county (Fonseca and Moreno;1988). The chief destinations for migrants from Gómez Farías are Watsonville and the San Francisco area (López Castro, 1986).

Return Behavior

Data on return migration behavior are scarce. Since the United States discontinued exit review in 1957, it has not been possibly to directly measure emigration from the United States. Indirect estimation suggests high levels of emigration among legal permanent residents as well as among the broader Mexico-born population. The Los Angeles project offers insights into migration circularity and migrants' plans to return to Mexico for migrants in the United States. A significant share of all migrant cohorts (27 to 43 percent) report that they plan to migrate back and forth between Los Angeles and their place of residence in Mexico. The share is higher, on average, for more recent cohorts (those last entering the United States after 1986) than for older cohorts. Among those last entering the United States after 1986, more than two thirds (67 percent) report they plan to stay in the United States, compared with only 27 percent of the most recent (1993-94) cohort. These findings suggest that circularity decreases with time in the United States. A recent study using the Mexican Migration Project data concluded that most migrants eventually return to Mexico (Public Policy Institute of California, 1997). These findings are influenced by return behavior of past migrant cohorts (e.g., *bracero* workers), however. Their relevance for predicting return behavior of the current cohort of migrants in the United States is not clear. Increased U.S. border enforcement may discourage return migration by making re-entry into the United States more difficult.

Demographic Profile of Migrants

The demographic profile of Mexico-to-U.S. migrants differs for sojourners and settlers; and it varies significantly across data sources and also over time.

Traditional sojourner flows were dominated by young, solo males. For example, Dagodag (1975), analyzing INS I-213 forms for apprehended migrants, found that over 90 percent of all apprehended immigrants were 40 years of age or younger, 92 percent were males, and 62 percent were single. In contrast, the legal-immigrant cohort of FY 1995 was 57% female, as wives of IRCA-legalized persons became permanent resident aliens.

Gender

The importance of males in Mexico-to-U.S. migration persists, although there is a trend toward more female migrants, and women dominate among new legal immigrants. Variation in gender patterns across migrant type and data source and over time is substantial, sometimes dramatic.

Most Mexico-based data sources show the share of males among Mexican migrants to be large. The few women interviewed by Gamio in the 1920s traveled to the United States to accompany their husbands or families. More recently, the ENEFNEU (1978-79) found that 83.9% of migrants to the United States were males. The ETIDEU (1984) placed the share of males at 89.1%.

Post-1990 estimates of the share of males among Mexican migrants range from 44 to more than 90 percent. High to very high proportions of males are found in surveys of circular migrants. In the EMIF data, women constitute only 1.88% of the return migrant flow and 5.6% of the south-north flow. Although the share of women is larger in the deported-migrant sample, it is nevertheless low (10.7%). The 1995 EMIF data found that the proportion of women in the north-bound flow (4 percent) was significantly lower than in the returning flow (10 percent). They also found that return rates were higher for men whose permanent residence is a rural community in Mexico than for men living in Mexican urban areas. The Zapata Canyon project found similarly high concentrations of males in undocumented-migrant flows for most years covered by the survey (97 percent in 1996). The ENADID found that 21.8% of the Mexican population that had ever lived or worked in the United States were women. The share for those who had lived in the United States over the previous five years was 23.9%, suggesting that the female share is increasing.[8] Among those who worked in the United States, the female share was 16.7%.

The share of women in circular-migrant cohorts decreases with cohort age. Women are 51.5% of migrants younger than 12 years of age, 30.7 percent of migrants aged 15 to 19, and only 12.3 percent of migrants in the 45 to 49 age group (ENADID, recent migrants).

The participation of women in migration also differs by region. In the ENADID data, it is lowest in region V (16.5%), followed by regions I (19%), II (20.2%) and

the Valley of México (20.3%). The highest female shares are in the border region, where women make up 26.9 percent of all migrants.

The 1985 UC-EDD farmworker survey indicates a gender composition of Mexican migrants that is similar to that constructed from some Mexican data sources. It found that males constituted 75 percent of all Mexican immigrant farm workers and 83 percent of unauthorized Mexican farm workers in California.

For the most part, shares of females among Mexican migrants are higher when estimated from data on relatively settled migrant populations. The proportion male among the migrants in the Michoacán surveys was .63 in 1983 and .56 in 1993. Thus, more women are joining the migration stream. This increasing participation of females in migration over time mirrors cross-section findings from the Mexican Migration Project. In the 19 communities surveyed by Durand, Massey, et al., the proportion male among migrants making their first trip was 73 percent. However, the greater the migration prevalence in a sending community, the lower the proportion male. The male share ranged from 93.3 percent at the lowest levels of community migration prevalence to 55.7 percent at the highest migration prevalence levels.

Disproportionately large male migrant shares are at odds with U.S. Census data, which put the share of males among all Mexican immigrants at 55.1 percent in 1990. This share varies slightly by immigration status and by period of entry. It is lower for pre-1980 immigrants (52.8 percent) than for 1980-89 immigrants (57.5 percent). It is also lower for naturalized citizens of Mexican origin (53.7 percent) than for noncitizens (55.5 percent). The single most male-dominated legal-status/period-of-entry category is the naturalized, 1980-89 cohort, which was 59.7 percent male. It no doubt reflects the effects of IRCA's legalization programs. The least male-dominated group is the naturalized, pre-1980 group (51.4 percent). All in all, Census data show Mexican immigration to be much more gender-balanced than do most Mexico-side or farmworker data sources.

INS data show that, among Mexico-born legal immigrants, women actually outnumbered men for eight consecutive years between 1964 and 1971, and they outnumbered men again in 1993 and 1994 (Table 3). Extreme peaks (e.g., 79 percent male in 1991) and valleys (e.g., 43 percent male in 1995) appear due to special legislation, such as IRCA legalization and the subsequent legalization of dependents. The LPS data indicate a male share of 59 percent among newly legalized migrants from Mexico. Nor surprisingly, this male share is almost identical to that of the naturalized, 1980-1990-entrant cohort in the 1990 Census.

Also visible in INS data on legal immigrants is the strong attractiveness of Mexico-born men as spouses for U.S. citizen women. For every year in which data were available except 1994, the proportion men among the Mexico-born immediate-relative spouses of U.S. citizens substantially exceeded fifty percent, fluctuating

between 56 and 62 percent in the years 1971-1979 (Volume 2, page 766, Figure 2), subsequently increasing to 63 percent in 1982 and to almost 70 percent in 1985, but dropping to 49.4 in 1994. In contrast, the majority of spouse immigrants from other countries are women, reflecting patterns of travel and military duty.

In short, large discrepancies in estimates of migrants' gender ratios appear to reflect differences in the subpopulations represented by each survey. For example, the Census and CPS capture more relatively settled immigrant families, in which the gender balance is close to 50-50, while the EMIF and ENADID focus on circular migrants, who by all accounts appear to be predominantly males.

Age

There is little variability in estimates of the average age of Mexican migrants across data sources. All post-1990 data, with the exception of INS data, yield estimates of the average age of Mexican migrants that are in the 29-to-33-year range. Mexico-born migrants to the United States are young, younger than nonmigrants in Mexico (with some exceptions), younger than migrants to the United States from other countries, and younger than the U.S. population at large. This relative youthfulness may reflect a number of distinct factors, including the presence of young pioneer migrants in early-stage localized migration streams and the presence of children in cohorts of legal immigrants (both children in migrating families and children sponsored by U.S.-citizen parents).

In 1970, Samora found that 85.8 percent of all first-time migrants were 30 years old or younger (Samora, 1971: 90). In 1978-79, according to ENEFNEU, the share of migrants younger than 30 years had fallen to 54.7%. In 1984, however, according to the ETIDEU, this share was 74.2%, with an average age of 26.2 years.

Estimates from more recent data sources indicate that the average ages of Mexican migrants are only slightly higher today. In ENADID, the average age of the population that migrated between 1987 and 1992 was 29.5 years. It was 31.6 in the population that worked in the United States and 19.4 in the population that did not. EMIF data find an average age of 31.7 years for the north-south flow of circular migrants. Deported migrants are younger: 25.4 years. Returning migrants are significantly older than outmigrants from Mexico.

Age differences between migrant flows originating in rural versus urban areas in Mexico are small in the EMIF data. Rural-urban age differences are larger in the ENADID data. Male migrants from rural areas averaged 32.5 years of age, compared with 26.8 years for migrants of urban origin. For female migrants, average ages were 30.2 years for rural and 23.3 for urban.

Age differences across regions of origin are also small. ENADID data show the youngest migrants originating from the Oaxaca-Guerrero region (25.1 years)

and the oldest from the northern region (26.9 years in region II and 26.1 in region III). Here, as in the EMIF data, the youngest groups of migrants hail from the regions that are newest to migration (regions IV and V, both with average ages of 28 years), and the oldest are from the more traditional migrant-sending regions (I and III, with average ages of 33 and 32 years, respectively). Among deported migrants, the picture is different; the lowest ages are associated with region III (24.6) and the highest with region V (27.7).

Average age of all (not only recent) migrants in the Michoacán surveys was 29 years in 1983 and 32 in 1993. The 1983 migrants were somewhat younger than nonmigrants, whose average age was 32, but the 1993 migrants were considerably older than nonmigrants, whose average age was 20. Unauthorized migrants, who comprised just over 58 percent of all 1993 migrants, were younger (28.5 years), on average, than documented migrants (37 years). In the 19 communities studied by Massey and Durand, the average age of migrants in the United States at their most recent trip was 29 years.

The 1990 U.S. Census of Population shows a median age for Mexican migrants of 31.5 years, compared with just under 34 years for the U.S. population as a whole. Median ages differ both by legal status and by period of entry into the United States. Median age in 1990 is strikingly higher for Mexican immigrants who reported they were naturalized U.S. citizens (41.7 years) than for noncitizens (30.4 years). Mexican immigrants are concentrated in the prime working-age groups. In the 1990 Census, 71.4 percent are between the ages of 20 and 54, compared with only 50.4 percent of the total U.S. population.

INS data show legal Mexico-born immigrants to the United States to be a young group at admission to permanent residence, with lower mean and median age than immigrants born elsewhere in every admission cohort since 1971. This may reflect larger family size as well as larger number of minor children of U.S. citizens. Mean age is higher among women than among men, but the difference is small except in 1994 (Table 3). In the LPS, average age for newly legalized migrants was 30 years, very close to the median age for the naturalized 1980-90 migrant cohort in the 1996 CPS but higher than that of the naturalized 1980-90 cohort in the 1990 Census.

Average age is higher for female than male migrants. In the U.S. Census of 1990, women born in Mexico have a median age of 31 years, compared with 29.3 for men. Among naturalized citizens, average ages for men and women are 28.8 and 29.4, respectively. A similar pattern emerges from the 1996 CPS, despite slightly higher ages. The median ages for men and women are 30.8 and 32.4, respectively;[9] for the non-naturalized group, median ages are 29.9 and 30.9, respectively. In the EMIF, average ages of migrants returning to Mexico are 32.6 for women and 31.7 for men; for deported migrants the average is 27 for women and 25.7 for men.

Women born elsewhere	31.58	18.01	19	29	42	99

NOTES: Figures for 1977, 1982, and 1994 are calculated from the INS microdata public use files; 1971 figures are calculated from a one-in-one-hundred sample of the immigrant cohort. Cohort sizes refer to the complete cohorts; missing data on sex or age may slightly reduce the size of the populations/sample on which calculations are based. Data for 1982 include 2300 Silva case adjustments. Data for 1994 exclude 6,022 IRCA-legalized persons but includes 34,074 legalization dependents. The minimum age observed in all groups in all years is zero, which represents infants less than one year old. Q(.) denotes the quantile function; thus, Q(.25) denotes the 25th percentile and Q(.5) denotes the median.

Among recent migrants enumerated by ENADID, however, the average age of women is less than the average for men: 26.9 versus 30.3 years, although for those who worked in the U.S. the gap is smaller, 30.7 compared with 31.8 years.

Among legal immigrants, age varies importantly across visa categories (Table 4). Average age is a full 10 years higher among immigrants admitted as siblings of U.S. citizens (in the 41-45 age range) than among employment-based immigrants (in the 31-34 age range). This difference may reflect both differences in the waiting time for visa issuance (e.g., visas are immediately available in all the skilled and professional employment categories except that for religious workers, for whom the wait has been only one or two years, but there is a 10-year waiting period for sibling visas and for the unskilled "Other Worker" visas) and differences in age at application (employment-based applicants in the unskilled category would be younger than other employment-based applicants, who must satisfy substantial educational and experience requirements). The youngest immigrants, excluding children, are those admitted as spouses of U.S. citizens (average age of 27 for men and 29 for women). Of course, the oldest are those admitted as parents of U.S. citizens (average age 63 for men and 60 for women).

The Mexican community surveys and INS data indicate that migrant ages may be increasing slightly. Average age of migrants rose from a mean of 29 in 1983 to a mean of 32 in 1993 in longitudinal studies in Michoacán. In the INS data, mean age of women increased from 21 in 1971 to 26 in 1994; mean age of men increased from 21 in 1971 to 24 in 1982, but it was less than 21 in 1994. Among these legal immigrants, increases in age may reflect longer waits for visa issuance and/or reduced family size. The Zapata Canyon data reveal decreasing shares of undocumented migrants in the "under 20" and "20-24" year-old groups, and a sharply rising share in the "25-29" group, between 1988 and 1996.

Marital Status

Data sources which include information on marital status uniformly indicate that most migrants are not single. For example, the ENADID found that 65.5% of those who went to the United States in the previous five years were either married or in union out of wedlock. There are differences in marital status between sexes, however: the average was 68.6 percent for men and 54.3 percent for women. The share of separated, divorced or widowed was higher for women: 14.8 percent, compared with 2.4 percent for men. The share of singles was similar for the two sexes: 27.9% for men and 31.1% for women. In the return flow of circular migrants enumerated by EMIF, the share of singles was also well under 50 percent, although it was different for men than for women. The share of singles was 40% for women and 33% for men. The only region of origin for which the share of singles exceeded

NOTES: Figures are calculated from the INS microdata public use files. Q(.) denotes the quantile function; thus, Q(.25) denotes the 25th percentile and Q(.5) denotes the median.

50 percent was region IV, where 53 percent of male migrants and 46.9 percent of female migrants were single.

In the LPS, 53 percent of newly legalized migrants from Mexico were married. The National Agricultural Worker Survey (NAWS) found that, in California, where 82 percent of all Seasonal Agricultural Service (SAS) workers are from Mexico, 66 percent of all SAS workers and 70 percent of male workers were married in 1991. (Separate estimates for the SAS workers who were Mexican migrants are not available.)

In the Michoacán surveys, 62% of all undocumented workers and 82 percent of all documented workers were married. The 1990 U.S. Census of Population reports that 59 percent of the Mexican-born male population and 61 percent of the Mexican-born female population 15 years or over was married. The married shares were only slightly lower for noncitizens than for those reporting as naturalized citizens. They were lowest for the most recent cohorts of noncitizens from Mexico. For example, among noncitizens, 45 percent of men and 58 percent of women entering the United States between 1980 and 1990 were reported as married in the 1990 Census.

The NIS Pilot Study of the 1996 legal immigrant cohort indicates that among those immigrants aged 25 years and older, the proportion married was higher for males than for females—92% versus 85%. This may reflect, in part, the larger numbers of males than of females admitted as spouses of U.S. citizens.

Schooling

At a time when the Mexican population had a very low average schooling level, especially in rural areas, Gamio found that migrants averaged fewer than five years of schooling and included a large share of illiterates. Despite significant increases in public spending on education during the 1960s, Samora found that 28 percent of migrants he surveyed never had attended school, and 90 percent had not completed primary education (Samora, 1971: 90). It appears that migrant education levels improved by the 1980s; in the 1984 ETIDEU data the share of illiterates was 14 percent for males and 17.6 percent for females.

All data sources provide evidence of less schooling among Mexican migrants than in the U.S. population as a whole and among other immigrant groups. Nevertheless, U.S. data sources as well as the ENADID find numbers of highly schooled individuals that are significant relative to the skilled population of Mexico and evidence of increasing average schooling among migrants over time. Moreover, estimates of average schooling using post-1990 data sources are uniformly higher than those based on earlier data, among both relatively settled migrant populations as well as circular migrants, and legal immigrants appear to have substantially higher schooling than unauthorized migrants.

The ENEFNEU (1978-1979) found an average schooling level among migrants of 4.9 years, slightly higher than that of the Mexican population over 14 years old (4.7 years). 34.3% had studied fewer than 4 years, and only 24.6 percent had studied 7 years or more. By contrast, in the U.S. population as a whole, only 3.4 percent had 4 years or fewer of schooling, 14.1 percent had between 5 and 8 years, and 82.5% had more than 8 years (CENIET, 1982).

The ENADID survey estimated that well over half (61.4 percent) of all persons 11 years or older who lived in the United States at any time during the 5 years prior to the survey had six years of schooling or fewer. 87.4 percent had 9 years or fewer of schooling. On the whole, women were better schooled than men: 55 percent of female migrants and 63.1 percent of male migrants had primary schooling or less; 9.1 percent of women and 4 percent of men had studied beyond high school (p*reparatoria*).

The EMIF data on circular migrants show an average of 7.6 years of completed schooling for women and 6.26 for men headed for the United States; for returning migrants, the averages are 7.09 years for women and 5.9 for women, and for deported migrants, 6.88 for women and 6.53 for men. These numbers indicate that, overall, female migrants are better schooled than male migrants, despite the fact that in the Mexican population as a whole schooling levels are lower for women than for men. ENADID found wide variability across regions of origin; for example, 19.1 percent of the migrants from the top three states had not completed a single year of school, compared with 3.8 percent of those from the northern border area. These regional differences are attributable in large part to differences in urbanization; the share of Mexicans who had not completed any schooling was considerably larger in rural (9.7 percent) than in urban (1.6 percent) areas. The EMIF data show average schooling levels of 5.96 years for migrants of rural origin and 7.02 years for migrants of urban origin in the northward migrant flows.

The ENADID study shows lower schooling levels for labor migrants than for migrants who did not work in the United States. Among recent migrants, 6.5 percent of those who worked and 3.6 percent of those who did not work had never attended school. The shares with some college education were 3.7% for labor migrants and 17.4% for nonlabor migrants. This may reflect students migrating to the United States to complete their studies.

Low average schooling among Mexican migrants is documented by U.S. farmworker data. The UC-EDD farmworker survey found that Mexican immigrant farmworkers had an average of 4.8 years of schooling; unauthorized migrant workers averaged 4.2 years. In California, the NAWS found that the median level of education among all SAS workers (of whom 82 percent were Mexico-born) was sixth grade in 1991. This includes all education received abroad and in the United States. Most farmworkers originate from rural communities in Mexico.

Schooling estimates from rural community surveys in Mexico mirror the low schooling levels found in farmworker surveys. Among the migrants in the Michoacán surveys, average schooling was only 4.1 years in 1983, but it increased to 5.8 years in 1993. Average schooling among nonmigrants decreased over the same period, from 4.5 to 4.3 years. Thus, while in 1983 migrants had less average schooling

than nonmigrants, the reverse was true in 1993. Undocumented migrants had significantly more schooling than legal migrants in 1993 (just under 7 years, compared with just under 5 years for legal migrants). This finding partly reflects increasing schooling levels in the populations of migrant-sending areas in Mexico—undocumented migrants made up most of the recent-migrant flow. However, it also reflects changes in the ways in which transnational migration selects on schooling. In the early 1980s, relatively well-educated villagers were likely to migrate, but their destinations were urban areas of Mexico rather than the United States, where returns to schooling for undocumented migrant workers were low.

In the Massey-Durand survey of 19 Mexican communities, average schooling among migrants at the time of their first trip to the United States was 5.8 years. These data, like data from the Michoacán surveys, suggest that schooling levels and the heterogeneity of migrants with respect to education are increasing over time. Migrants from the highest migration-prevalence communities averaged more than 50 percent more years of completed schooling (and nearly twice the educational diversity) than migrants from the lowest migration-prevalence communities. An upward trend in high school graduates among undocumented migrants is one of the most salient findings from the Zapata Canyon project.

The 1995 EMIF data reveal that north-bound migrant flows are better educated than returning flows. The share in the low-education (0-to-6-year) category is lower for north-bound migrants. The share in the higher education (7-or-more-year) category is higher for out-migrants from Mexico than for returning migrants. Nevertheless, for migrants originating in urban areas of Mexico, the north-bound flow is less educated, on average, than the returning flow.

U.S. Census data indicate that, among the Mexico-born population aged 25 or older and enumerated in 1990, 28.2 percent had less than a fifth-grade education, compared with 2.7 percent for the U.S. population as a whole. More than three-quarters lacked a high-school diploma, compared with just over 18 percent of the U.S. population; 11.6 percent were high school graduates with no further schooling, and 2.1 percent were college graduates with no postgraduate education, compared with 30.0 and 13.1 percent, respectively, of the U.S. population. The proportion of Mexico-born persons in the United States holding doctorate degrees was 0.14 percent, compared to 0.76 percent for the United States as a whole. The absolute number of Mexico-born doctorates, however, was 3,824, a rather large number for a small country. Note that Census data do not reveal whether these are persons undergoing further training or engaged in postdoctoral work with nonimmigrant visas as opposed to permanent residents of the United States.

Overall, the 1980-89 cohort of Mexican immigrants had higher levels of schooling than the pre-1980 cohort in the 1990 U.S. Census. The share with less than a fifth-grade education was lower for the more recent immigrant group (26.9,

compared with 29.0), and in most cases the shares with post-secondary schooling were higher for the more recent group, as well. At the upper end of the educational spectrum, 4.4 percent of recent (1980-89) Mexican migrants had a Bachelors, Masters, Professional School, or Doctorate degree, compared to just over 20 percent of all U.S. residents 25 years or older. Recent migrants were more than twice as likely as pre-1980 migrants to have a professional degree (1.2 percent, compared with 0.4 percent), more than two thirds as likely to have a Masters degree (0.7 percent, compared with 0.56 percent), 50 percent more likely to have a Doctorate degree (0.17, compared with 0.12), and more than one fifth as likely to have a Bachelors degree (2.4 percent, compared with 1.9 percent). Naturalized citizens almost always have smaller shares in the low-education categories and larger shares in the high-education categories than noncitizens; however, these differences are not large in most cases.

Among persons reporting they were naturalized citizens, the share with less than a high-school education is lower in the 1996 CPS (52.9 percent) than in the 1990 Census (67.5), and the share with at least a Bachelor's degree is higher in the CPS (6.5 percent, compared with 4.9 percent in the Census). Differences between the Census and the 1996 CPS are particularly large in naturalized, 1980-89 entrants with college degrees; the share with a Bachelor's degree is 7.5 percent in the CPS and 2.0 percent in the census. However, the CPS data also indicate low average schooling among Mexican migrants entering the United States after 1990. Seventy-four percent of the post-1990 group had less than a high-school education, compared with 69 to 70 percent of the pre-1990 cohorts.

Migrant cohort-specific schooling levels differ sharply between the 1990 Census and 1996 CPS. For example, for both immigrant-status groups, the share of 1980-89 entrants who are high-school graduates is higher in the 1996 CPS than in the 1990 Census. The same is true for the share of high-school graduates among pre-1980 entrants.

Average schooling for newly legalized migrants in the LPS was 6 years, and 59 percent had 6 or fewer years of schooling. Only 5 percent had more than a high-school education.

NIS data on the FY 1996 cohort of legal immigrants indicate that Mexico-born legal immigrants—or at least those admitted to permanent residence in 1996—are considerably better educated than previously thought. Among persons aged 25 and older, 35% are high school graduates and 14.7% are college graduates, compared to 26% and 6.3%, respectively, among comparably-aged recent entrants enumerated in the 1990 Census (Table 5). Moreover, 9.1% of the legal immigrants have completed 17 or more years of schooling, compared to 3% of those enumerated in the 1990 Census. School enrollment rates among persons 18 to 24 years of age are also higher among legal immigrants than among the census-enumerated—25%

Table 5
Schooling Distributions and School Enrollment Rates, Persons Born in Mexico: NIS 1996 Cohort and 1990 Census Recent Entrants (Entered 1987-90)

Schooling Characteristic	NIS 1996 Cohort	U.S. 1990 Census
A. Years of Schooling Completed, Persons Aged 25 and Over		
Less than 5 years	21.2	28.1
5-8 years	29.5	28.6
9-11 years	14.6	17.6
12 years	11.0	11.1
13-15 years	9.1	8.3
16 years	5.7	3.3
17-18 years	5.3	1.1
19+ years	3.8	1.9
Mean years	8.9	–
Median	7.0	–
B. School Enrollment, Persons Aged 18 to 24 Years	25.4	15.7

NOTE: 1990 Census figures for foreign-born are drawn from published tabulations (1990 CP-3-1).

SOURCE: Jasso, Massey, Rosenzweig, and Smith (1997).

versus 16%. Thus, the U.S. Census, given that it includes both legal and unauthorized migrants, provides a portrait of schooling that seriously understates the schooling of legally admitted permanent residents.

The FY 1996 legal immigrants born in Mexico have a rate of college graduation approaching that among the native-born—15% compared to 20%—and a higher rate of advanced schooling than the native-born—9% compared to 7% (Tables 5 and 6). On the other hand, legal immigrants born in Mexico have a substantially larger proportion with low levels of schooling than either immigrants born elsewhere or the native-born U.S. population—65% without a high-school education compared to 34% among all the FY 1996 legal immigrants and 23% among the native-born U.S. population in 1990.

Table 6
Schooling Distributions and School Enrollment Rates: NIS 1996 Cohort, 1990 Census Foreign-born (Entered 1987-90), and 1990 Census Native-born

Schooling Characteristic	NIS 1996 Cohort	Foreign-born 1990 Census	Native-born 1990 Census
A. Years of Schooling Completed, Persons Aged 25 and Over			
Less than 5 years	6.8	12.1	1.8
5-8 years	12.7	11.9	6.9
9-11 years	14.1	12.9	14.3

SOURCE: Jasso, Massey, Rosenzweig, and Smith (1997).

Schooling levels among legal immigrants also differ substantially across visa categories, and patterns among the Mexico-born are qualitatively similar to patterns among those born elsewhere (Table 7). In general, and as expected, immigrants with employment-based visas have the highest schooling levels—averaging 16 years for both Mexico-born and the 1996 cohort as a whole. Immigrants admitted as parents of U.S. citizens have the lowest average schooling, 7.5 years on average for the cohort as a whole and 4.5 years for the Mexico-born. Immigrants admitted as spouses and siblings of U.S. citizens have intermediate average schooling levels, with spouses higher, reflecting screening implicit in their selection as mates by U.S. citizens. Although the qualitative patterns are similar, there are some quantitative differences. For example, the difference between the average schooling of

Table 7
Years of Schooling Completed Among Mexico-born and All Immigrants Aged 25 Years and Over at Admission, by Visa Class: NIS 1996 Cohort

Visa Class	All Immigrants		Born in Mexico	
	Mean	S.D.	Mean	S.D.
Spouse of U.S. citizen	13.6	4.6	12.7	4.9
Parent of (adult) U.S. citizen	7.5	5.1	4.5	4.3
Sibling, principal and spouse	13.4	5.4	7.5	2.1
Employment, principal and spouse	16.1	4.3	16.0	6.1
Refugee/asylee, principal and spouse	13.1	4	-	-
Diversity, principal and spouse	14.5	3.3	-	-
Other	11.1	4.7	7.3	3.9
All Immigrants 25 and over	12.7	5.1	8.9	5.5

NOTE: Figures are for all immigrants in the NIS 1996 cohort (July and August 1996) who were aged 25 years and over at admission to permanent residence.

Mexico-born spouses and spouses born elsewhere is smaller (not quite one year of schooling) than the difference between sibling immigrants born in Mexico and those born elsewhere (almost six years different in average schooling).

English Language Skills

Not surprisingly, information on English-language skills is available primarily from U.S.-side data sources. Data from the 1990 U.S. Census indicate that, among Mexico-born persons aged 5 years and older, 71 percent report not speaking English "very well." As would be expected, the percentage with poor English skills is larger for those who entered the United States during the ten-year period prior to the Census (78.5 percent) than for those who entered before 1980 (63.2 percent).

In the 1990 Census, English language deficiency is lower among those who report they are naturalized citizens (57.5 percent) than among noncitizens (74.6 percent). It is highest for the 1980-89 cohort of non-naturalized migrants (80 percent). The LPS found that it was higher still for the newly legalized group of migrants

from Mexico; only 10 percent of these migrants reported speaking English well. English language deficiency appears to be particularly high among farm workers. The 1990 NAWS found that only 7 percent of Mexican-born farmworkers could speak English, and only 4 percent could read it. Mexicans represented 57 percent of the total U.S. workforce in seasonal agricultural services (SAS) and 92 percent of the foreign SAS workforce in 1990.

The NIS data on FY 1996 legal immigrants indicate that over half of those aged 18 years and older speak English "average or so-so" or better (Table 8). As would be expected, immigrants with previous experience as unauthorized migrants have lower proficiency in English—while 51% of those with EWI experience report speaking English "not very well" or "not well at all," 44% of those without measured EWI experience do so.

Marriage and Family

Immigrant Spouses, Parents, and Minor Children of U.S. Citizens

Information on marriage and family for Mexican migrants is available almost exclusively from U.S. Census and INS data. The largest single component of normal-flow legal immigration of the Mexico-born consists of the immediate relatives—spouses, minor children, and parents—of adult U.S. citizens. The largest component

Table 8
English Language Skill Among Immigrants Born in Mexico Aged 18 Years and Over at Admission, by Whether They Ever Entered the United States Without Inspection (EWI): NIS 1996 Cohort

English Language Proficiency	All	No EWI Experience	Some EWI Experience
Speaks English "very well"	9.1	12.9	5.6
Speaks English "fairly well"	9.7	16.7	5.6
Speaks English "average or so-so"	32.9	26.2	38.1
Speaks English "not very well"	17.9	13.2	21.4
Speaks English "not well at all"	30.3	30.9	29.3

NOTE: Respondents classified as having EWI experience met at least one of two criteria: (i) their first trip to the United States was without legal documents, or (ii) adjustment to permanent residence was from an EWI status.

of immediate-relative immigration consists of the spouses of U.S. citizens. Mexico is the leading source of spouses of U.S. citizens.

While the number of visas under the preference system is limited both worldwide and per country (20,000 prior to the Immigration Act of 1990; 7 percent of the total annual family-sponsored and employment-sponsored preference limits subsequently—e.g., 31,627 for FY 1996), the number of immediate relatives has no ceiling. In FY 1985 (the only year for which data are available on the nativity of the U.S.-citizen sponsors), 73 percent of all Mexico-born immediate relatives were sponsored by native-born U.S. citizens. In contrast, worldwide, 64 percent of all immediate relatives were sponsored by native-born U.S. citizens.

Immediate-relative immigration from Mexico has exceeded 20,000 every year since FY 1978 and has exceeded 30,000 every year since FY 1982 except for FY 1992 and FY 1995; it peaked during Fiscal Years 1986-1988, when it exceeded 40,000 per year.

Spouses of U.S. Citizens

Most of the immediate relatives from Mexico are spouses of U.S. citizens; the spouse flow alone exceeded 30,000 in FYs 1986-1988. Time series data indicate a strong decline since FY 1989, to lows of 15,350 in FY 1992 and, after an upturn, to 13,841 in FY 1995.

Sex Ratio Among Spouses and Sponsors

As noted above, INS legal-immigrant data indicate that marriage to a U.S. citizen is predominantly an activity involving U.S. women and Mexican men. In the period FY 1971-1979, the proportion husbands fluctuated between 56 percent and 61.8 percent. Microdata from the FY 1982 cohort indicate that the proportion husbands was 63.4 percent, and a probability sample drawn by the General Accounting Office (GAO) for the FY 1985 immediate-relative immigrants indicates that the proportion husbands in 1985 was 69.85 percent. However, the proportion husbands declined to 49.4% in 1994, and in the NIS cohort of 1996 to 44.2%.

Nativity of U.S. Citizen Sponsors of Spouses

The GAO data also indicate that a substantial majority of the U.S. sponsors of spouses in FY 1985 were U.S. citizens by birth—almost 78 percent (Table 9). Among the male sponsors of Mexican brides, 73.17 percent were born in the United States, and an additional 4.88 percent were U.S. citizens by birth, born to Americans abroad; among the female sponsors of Mexican husbands, 74.74 percent were born in the United States, and an additional 2.11 percent were born abroad to U.S. parents. For

Table 9
Sex and Citizenship Type of the U.S. Citizen Sponsors of Immediate Relatives, for All Immediate Relatives and Those Born in Mexico: Evidence from the GAO FY 1985 Immediate-relative Immigrants File

Sponsor's Citizenship Type	Spouses	Own Children	Adopted Children	Parents
A. All Immediate-relative Immigrants				
Birth-citizen, Born in U.S.	76.28	52.57	97.89	2.91
Birth-citizen, Born Abroad to U.S. Parent(s)	4.02	12.64	0	1.65
Birth-citizen, Place of Birth Not Known	0.18	0	0	0
Naturalized Immigrant	19.52	34.79	2.92	95.44
Total Sponsored Immigrants	124,093	25,778	9,286	38,986
B. Immediate-relative Immigrants Born in Mexico				
Birth-citizen, Born in U.S.	74.26	48.48	0	6.67
Birth-citizen, Born Abroad to U.S. Parent(s)	2.94	24.24	0	6.67
Birth-citizen, Place of Birth Not Known	0.74	0	0	0
Naturalized Immigrant	22.06	27.27	0	86.67
Total Sponsored Immigrants	28,957	6,425	137	2,464
C. Immediate-relative Immigrants Born in Mexico, Sponsored by U.S. Men				
Birth-citizen, Born in U.S.	73.17	48.00	0	11.11
Birth-citizen, Born Abroad to U.S. Parent(s)	4.88	20.00	0	0
Birth-citizen, Place of Birth Not Known	2.44	0	0	0
Naturalized Immigrant	19.51	32.00	0	88.89
Total Sponsored Immigrants	8,730	4,868	NA	1,479

Table 9 (Continued)

Sponsor's Citizenship Type	Spouses	Own Children	Adopted Children	Parents
D. Immediate-relative Immigrants Born in Mexico, Sponsored by U.S. Women				
Birth-citizen, Born in U.S.	74.74	50.00	0	0
Birth-citizen, Born Abroad to U.S. Parent(s)	2.11	37.50	0	16.67
Naturalized Immigrant	23.16	12.50	0	83.33
Total Sponsored Immigrants	20,227	1,557	NA	985

NOTE: All figures are sample estimates except the total numbers of immigrants in Panels A and B. All naturalized-citizen sponsors of Mexico-born immediate relatives were themselves born in Mexico except for 13.64 percent of the women sponsors of spouses, of whom two-thirds were born in Germany and the remaining one-third in Cuba. Of the birth-citizens born abroad who sponsored Mexico-born immediate relatives, all were themselves born in Mexico.

both Mexico-born spouses of U.S. citizens and those born elsewhere, the NIS Pilot Study registers smaller proportions of native-born sponsors—66% of the sponsors of Mexico-born spouses and 52% of sponsors of spouses born elsewhere are native-born U.S. citizens.

Nativity of U.S. Citizen Sponsors of Parents and Minor Children

Not surprisingly, the overwhelming majority of sponsors of Mexico-born parents—almost 87 percent in the GAO data—are naturalized citizens (Table 9). Almost half of all sponsors of minor children (excluding orphans) were born in the United States, and an additional 24 percent were born abroad to U.S. parents.

Migrant Families and Family Size

As noted above, ENADID and EMIF data place the share of Mexican migrants who are single at between 28 and 40 percent, depending upon the data source and gender, with female migrants being significantly more likely to be single than male migrants.

LPS data on the IRCA (Section 245A)-legalized aliens indicate that the Mexico-born had the highest average household family size—3.8 persons, compared with 2.8 for the rest of the group.

The 1990 Census data show 18.8 percent of Mexican immigrant households having only 1 or 2 persons, 47.7 percent having more than 5 persons, and 17.4 percent having 7 or more persons. The share of small (1-or-2-person) households is larger for pre-1980 immigrants (20 percent), but the share of large (7-or-more-person) households is similar across migrant-cohort groups. Noncitizen households are less likely to be small (16.6 percent are 1-2-person households) and more likely to be large (18.8 percent have 7 or more persons) than households headed by persons reporting themselves naturalized.

Fertility

Mexico-born women enumerated in the U.S. Census have higher fertility than the U.S. average in all age groups. Mexico-born women 15 to 24 years of age averaged .63 children ever born, compared with .30 for all U.S. women in this age group, and women 25 to 34 years of age averaged 2.13 children ever born, compared with 1.33 for all women. Mexico-born women 35 to 44 years old averaged 3.29 children ever born, compared with 1.96 for all U.S. women. In the 25-34-year age group, fertility is lower the more recent the year of entry. Children ever born for this age group range from 2.32 for pre-1980 entrants to 1.69 for 1987-90 entrants. There is no discernible fertility pattern by year of entry for the oldest group. For the youngest group, children ever born is .56 in the pre-1980 entry cohort, peaks at .85 in the 1982-84 cohort, then declines to .52 in the 1987-90 cohort.

Among legal immigrants in the FY 1996 cohort, the average number of children is 2.5, with an average of 2.2 children residing in the United States and the rest abroad.

Naturalization

Traditionally immigrants from Mexico had low naturalization rates, rates exceeded by immigrants from every country except Canada. Annual naturalizations hovered between 6,000 and 10,000 during the 1960s and 1970s, but in the decade after the preference category system of visa allocation was extended to the Western Hemisphere—effectively augmenting the sponsorship privileges of citizens with roots in this hemisphere—naturalizations more than tripled. Since then, naturalizations have continued to increase, to 39,310 in 1994 and 67,238 in 1995 (see Figure 3 in Volume 2, page 767). Note that these figures understate the number of

naturalizations, as the data do not include children under the age of 16 who derive naturalization from their naturalizing parents.

Naturalizations are expected to continue to increase, due to the confluence of several factors: (i) the backlog pressure on the categories of spouse and minor children of permanent resident aliens, intensified by the IRCA legalizations; (ii) the Green Card Replacement Program, initiated in 1992, which requires that permanent resident alien cards issued before 1978 be replaced and which, given that the requisite investment of time and money is no more for applying for naturalization than for replacing the green card, has led many immigrants to choose naturalization; (iii) initiation of an expiration date, 10 years after issuance, on green cards issued since 1988, which is also likely to lead immigrants to choose naturalization over green-card renewal; (iv) recent U.S. legislation which dramatically reduces the civil rights and social entitlements of non-naturalized immigrants; and (v) recent amendment of the Mexican Constitution which provides that Mexican nationals who become naturalized citizens of another country do not forfeit Mexican nationality.

Overall, in the period 1961-1995, a total of 470,515 Mexican nationals naturalized; this number omits children deriving U.S. citizenship from the naturalization of their parents. Interestingly, more women than men have naturalized—almost 21,000 more in the 1961-1995 period. Time series data indicate that the proportion male was less than half in every year since 1961 except, trivially, in 1964 and 1965 and in 1990-1993.

Naturalization rates have also increased steadily, and, although lower than worldwide averages, have overtaken the rates for immigrants from Canada and Germany. Among Mexico-born immigrants aged 16 and over at admission, 17.6 percent of the 1977 cohort and 11.9 percent of the 1982 cohort had naturalized by October 1993; the corresponding figures for the worldwide cohorts are 41.5 and 37.6 percent (INS 1994 Statistical Yearbook, pp. 132-133).

The 1990 U.S. Census counted almost 1 million Mexico-born persons who reported that they were naturalized citizens of the United States. This number constitutes 22.4 percent of the total enumerated Mexico-born population but, of course, a larger fraction of the relevant population—i.e., the total Mexico-born population in the Census includes persons who are not eligible to naturalize, not only legal immigrants who are too recently arrived to have met residency requirements but also nonimmigrants and undocumented migrants. This figure, however, is thought to be a serious overestimate (Clark and Passel 1997).

Participation in Migration Networks

U.S. immigration law virtually enshrines migration networks, given that the majority of non-refugee visas are allotted to relatives. The main visa categories

that do not require a network are the employment categories and the spouses of U.S. citizens—though networks may underlie the former and may emerge from the latter.

Nearly all data on migration networks are from community studies in Mexico. Sixty-seven percent of all individuals enumerated by the 1993 Michoacán survey had at least one immediate family contact in the United States. Those with kin networks averaged 1.6 contacts each. In one village included in the longitudinal Michoacán survey, the share of individuals with at least one family contact in the United States increased from 56 percent in 1983 to 80 percent in 1989.

Characteristics of Migrant-Sending Households in Mexico

Information on characteristics of migrant-sending households in Mexico is available from community survey data. Migration networks, or access to family contacts in the United States, are almost universally found to be the most important single household variable influencing migration and one of the households' most important economic and social assets. "Ownership" of migration networks and past migration experience are fundamental characteristics of migrant households in Mexico. The most detailed data on these as well as other characteristics of migrant-sending households come from community studies in Mexico. It is not possible to generalize findings from surveys of small numbers of communities to the population-at-large of migrant-sending households. Nevertheless, some patterns emerge that provide insights into changes in characteristics of migrant-sending households at different points in the migration process and differences in characteristics between households that send migrants to the United States and those that do not. The verdict on whether and to what extent these findings can be generalized will have to await the availability of new community-survey data from Mexico.

Mexican Migration Project data suggest that landlessness is positively related to the likelihood of undertaking a first trip to the United States. That is, controlling for personal characteristics, first-time migrants are significantly more likely to come from households with limited or no landholdings than from large-holder households. They are also more likely to have fathers with U.S. migration experience. The probability of taking subsequent trips, however, was found to be unrelated to these household characteristics. It depended entirely on the individual's migratory experience and on migration networks (Massey, 1987). A comparison of land ownership across the 19 communities surveyed in the Mexican Migration Project suggests that migrants are more likely to come from landless households in communities with high levels of migration prevalence. These data

also indicate that, although the vast majority of migrants come from households in Mexico that do not own businesses, the share that do is not negligible—particularly at the lowest (9.3 percent) and highest (8.1 percent) community migration-prevalence levels.

The Michoacán Project data reveal significant differences in household characteristics between migrants and nonmigrants. The 1983 surveys found that Mexico-to-U.S. migrants, on average, came from larger families (9.1 adult members 13 years of age or older compared with 8 for non-Mexico-to-U.S. migrants), with above-average landholdings (7 hectares, compared with 5 for nonmigrants), and relatively wealthy households (3,470 in 1982 pesos, compared with 2,190 for nonmigrants). However, for the most part they were not the most privileged families in migrant-sending villages. In fact, controlling for household income and wealth, migrants were significantly more likely to come from households that were "relatively deprived" within their village reference group—i.e., located at the bottom-to-middle of the village income distribution. Even for otherwise similar households, migration behavior is not uniform across socioeconomic (e.g., village) settings.

The larger, 1983 Michoacán study, like its predecessor, found that both undocumented and documented migrants originate from households in Mexico with above-average family size (11 and 12 family members for the two migrant groups, respectively, compared with 10.7 for the full sample). They also come from families with above-average education (.86 and .84 members with some secondary schooling, compared with .76 for all households); with more family members with migration experience (5.6 and 7.3 members, respectively, compared with 3.4 for all households); larger landholdings (1.9 and 2.4 hectares, compared with 1.4 for all households); and more wealth, as indicated by the value of animal herds (5,309 and 8,781 in 1992 pesos, compared with 4,148 for the full sample). The differences between migrant and nonmigrant households implied by these numbers reflect both the selectivity of migration on family characteristics and impacts of past migration experience on the accumulation of family assets. For example, one study (Taylor, 1992) found a significant positive effect of past migration on the accumulation of livestock.

A common characteristic of migrant households in Mexico is their receipt of remittance income from migrants in the United States. The LPS found that 66 percent of newly legalized Mexican migrant families remitted, and average remittances to Mexico were $1,304, or seven percent of the total income of Mexican migrant families in the United States. Average remittances to Mexico were higher than to any other region. For example, average remittances were $1,144 to Central America, $930 to other western hemisphere countries, and $874 to eastern hemisphere countries. Mexico Migration Project data on 22 migrant-sending communities show that, in the 12 months prior to the survey, household heads who were

migrants remitted an average of US $2,383, and non-heads remitted an average of $2,100. Returning migrants who were household heads brought back an average of $1,392 in savings; non-heads brought back an average of $858 (Massey and Parrado, 1994). Most surveys that gather data on migrant remittances do not provide information on total incomes in surveyed households, making it impossible to ascertain the share of remittances in total incomes of migrant-sending communities. Nevertheless, available evidence suggests that migrant remittances and savings represent an important share of total income in many migrant-sending households and regions. For example, income remitted by migrants in the United States accounted for 17 to 20 percent of total household income in the Michoacán Project villages, both in 1982 (Stark, Taylor and Yitzhaki, 1986) and 1988. Studies of villages in other regions of Mexico suggest typical international remittance shares on the order of 15 to 25 percent; e.g., see Taylor and Yunez (1995).

Labor-Market Characteristics

Migrants' occupational configurations, both in Mexico and in the United States, differ markedly by data source and by gender. In general, data on circular migrants show a stronger attachment of migrants to agricultural work, both in the United States and in Mexico, prior to migrating. Data on relatively settled populations indicate that most Mexican migrants are employed outside of agriculture, particularly in manufacturing and services. Data from nearly all sources suggest an increasing diversity of employment, both before and after migration, over time, as well as growing orientation towards urban jobs.

Work in Mexico Prior to Migration

At the start of the 1900s, agricultural workers were predominant in migrant flows. This trend continued during the Bracero Program. In the years following the Bracero Program, however, the share of agricultural workers in migrant flows has diminished. In 1971, Samora found that only 57% of migrants had worked in agriculture prior to migrating. The ENEFNEU survey found a similar share of agricultural workers (58.5%); 15.1% had held industrial jobs and 23.5% had worked in services. These shares contrasted with those for the Mexican population as a whole (39.3%, 21.4%, and 38.7%, respectively). The ETIDEU found that by 1984 the share of the primary sector had fallen to 39.4 percent. Only 5.6 percent of women worked in agricultural jobs, 30.6 percent worked in industry, and 60.2 percent in services (mostly domestic).

Most migrants had work in Mexico prior to migrating. In the ENEFNEU, only 20% did not work and only 3.2% were openly unemployed in Mexico prior to

migrating. The share without work was higher in the 1994 EMIF: 27.4% of returning migrants, 21.3 percent of deported migrants, and 32.4 percent of migrants en route to the United States did not work during the 30 days prior to migrating from Mexico. In the large majority of cases, migration cannot be attributed to an absence of employment in Mexico.

EMIF data show a relatively high share of agricultural workers in circular migrant flows. More than half of all male migrants in both the south-north and north-south flows worked in agriculture prior to migrating (57.6 and 55.2 percent, respectively). This share is lower in the deported-migrant flow (35.5 percent). About 25.6 percent of returning migrants and 21.4 percent of south-north migrants were in industrial jobs prior to migrating. The shares in service-sector jobs for the two flows were 19.2 percent and 18.3 percent, respectively. Activities associated with the urban sector absorbed more of the deported-migrant flow prior to migrating: 33.9 percent were in industrial jobs (20.5 percent in construction), and 30.5 percent were in service-sector jobs. The shares of undocumented migrants employed in farm work and in urban jobs, respectively, were 39 percent and 56 percent in the Zapata Canyon project data for 1996. Both of these shares were appreciably lower—and the share unemployed in Mexico higher—in 1988 than in 1996.

The high share of migrants employed in construction jobs prior to migrating—16 to 17.4%—suggests that the migration propensity is higher for this group than for other workers in manufacturing. Construction jobs in Mexico are characterized by a high degree of instability, low wages and poor working conditions.

In the EMIF study, 61.8% of women migrating northward worked in Mexico prior to migrating. The shares for deported and returning migrants were 46.2% and 38.9%. Most female migrants worked in services (68 percent of returning migrants, 64 percent of deported migrants, and 44 percent of north-bound migrants; see EMIF). Among north-bound female migrants, previous employment was nearly equally divided between industrial and service (41 percent) jobs. Sectors of employment prior to migrating vary across region. For example, agriculture employed 66.7%, 61.4% and 45.6%, respectively, of north-bound migrants, return migrants, and deported migrants born in rural areas.

Occupations of Return Migrants in Mexico

The majority of return migrants do not do agricultural work. The ENADID data reveal that most return migrants in urban areas of Mexico (61 percent) are wage workers, while most return migrants in rural areas are either self employed (32.3 percent) or non-agricultural wage workers (38 percent). Only 19.5 percent of return migrants in rural areas and 6.5 percent in urban areas are agricultural wage

workers. Non-remunerated work absorbs 9 percent of return migrants in rural areas and 3 percent in urban areas. Very few (1.1 percent in rural zones and 3.7 percent in urban zones) are businessmen (*empresarios*).

Predictably, the most urbanized regions (II and IV) have the largest shares of nonagricultural workers among return migrants. Regions III and V have the largest shares of non-remunerated workers (11.8% and 9.4%, respectively, similar to those regions' agricultural-worker shares). These are regions where subsistence farming is predominant. Among women, all regions display a high level of unemployment prior to migration. The highest is region III (73 percent) and the lowest, Oaxaca-Guerrero (63.7 percent). The largest share of women in nonagricultural jobs is found in the border zone (74.6 percent), due no doubt to the presence there of *maquiladoras* employing large numbers of female workers.

Work in the United States[10]

Work is a primary motivation for migrating to the United States. Of those who have lived in the United States, 81.5% have worked there (ENADID). The EMIF found that 88.8 percent of voluntarily returning migrants had worked in the United States. In addition, the ENADID survey found over 1 million people who declared having worked in the United States without living there. The labor-migrant share is higher for men (91.6 percent) than for women (53.8%). The LPS found a labor market participation rate of 95 percent for Mexican men and 63 percent for women, with unemployment rates of 2.3 percent and 6.6 percent, respectively. Average hours worked per week were 44 for men and 40 for women.

Data on employment of Mexican migrants in the United States reveal an increasing diversity of jobs over time. At the end of the 1800s and up through the end of the Bracero Program, Mexican migrants were employed primarily in agriculture.

The ENEFNEU study fount that, in 1978-79, only 37.1 percent of migrants worked in the agricultural sector; 24.8 percent were employed in industry and 37.6 in services (CENIET, 1982, 144). ETIDEU data show a larger share in agricultural jobs (45%), reflecting a relatively high incidence of farm work for undocumented (deported) migrants, the population represented by that survey.

Nevertheless, Census and CPS data reveal high levels of unemployment for Mexican migrants. The 1990 Census reports an unemployment rate of 11.3 percent for Mexican migrants, compared with 6.3 percent for the U.S. population at large. The 1996 CPS reports a larger unemployment gap: 21.9% unemployment for Mexican migrants, compared with 5.9% for the population as a whole. Of course, Census and CPS data include substantial numbers of persons without permission to work, some of whom may simply be obeying the law—for example, spouses of a variety of legal nonimmigrants, such as students (F visas), temporary workers

(H and O visas), intracompany transferees (L visas), artists and entertainers (P visas), religious workers (R visas), and treaty traders and investors (E visas). Thus, the increase in unemployment among Mexico-born persons enumerated in the CPS in 1996, relative to the 1990 Census, may reflect increasing numbers of legal nonimmigrants. It may also reflect increasing numbers of persons who may be working illegally and reporting that they do not work.

Data sources differ sharply on the distribution of migrant jobs across sectors. EMIF data show that more than half (52.7 percent) of all returning migrants were agricultural workers in the U.S., with industry (24.6 percent) running a distant second. Two thirds of the migrants reported in industrial jobs worked in construction. Of the 22.7% who worked in services, 5.8% held domestic-service jobs. The largest share of deported migrants worked in services (47.6 percent); 32.1 percent of deported migrants had been agricultural workers.

The agricultural employment share is larger in EMIF data than in most other data sources, including the U.S. Census and INS data and data from community studies in Mexico. This may reflect greater tendency towards agricultural work among circular migrants than among more settled ones. Today, although Mexican migrants are the majority of U.S. farmworkers, U.S. agriculture absorbs far less than half of all Mexican immigrants.

Among the migrants in the 1983 Michoacán survey, 90 percent worked in light manufacturing and service jobs in and around California's San Fernando Valley. This was in contrast to the older cohorts of returned migrants, who worked almost exclusively in U.S. agriculture—first as *braceros* and later as undocumented migrants. In one of the villages, a Purépecha (Tarascan)-speaking community that was almost entirely bypassed by the Bracero Program, households did not participate heavily in Mexico-to-U.S. migration at the time of the 1983 survey; only a handful of individuals from this village worked in the United States in the early 1980s, almost all as H-2 workers harvesting tobacco in Virginia. By 1993, many households in this village had family members working in the United States, mostly in manufacturing and service jobs in Southern California, a few harvesting apples in Washington and Oregon, but no H-2(A) workers in the Eastern United States.

The Zapata Canyon project data show evidence of an upward trend in urban-sector employment for undocumented migrants, particularly in construction and services.

INS microdata on the FY 1977, 1982, and 1994 immigrant cohorts indicate that approximately half of the prime-age men are in the operators-fabricators-laborers classification (Table 10). The proportion in farming-forestry-fishing was highest in 1982 (9.9 percent) and lowest in 1994 (4.9 percent). The combined executive and professional classification was also highest in 1982 (7.0 percent) and lowest in

Table 10
Occupational Distributions, Immigrants Born in Mexico, Aged 21-65 at Admission to Permanent Residence: FY 1977, 1982, 1994 Cohorts

Summary Occupation Group	FY 1977 Cohort		FY 1982 Cohort		FY 1994 Cohort

Average occupational earnings, 1979$	16,617	16,149	16,492	16,144	16,251	15,614

NOTE: Panel B earnings figures for 1977 exclude 3 cases for which detailed occupation could not be unambiguously ascertained.

1994 (4.75 percent). The proportion employed in service occupations fluctuated between 10 and 15 percent. Among women, the proportion reporting an occupational title increased steadily, more than doubling between 1977 (22.5 percent) and 1994 (44.7 percent).

The 1977 and 1982 INS data, which include naturalization information, suggest both that those who naturalize are drawn from among the more highly skilled and that those who naturalize experience occupational upgrading during

the years between admission to permanent residence and naturalization (Table 11). Moreover, among women, labor force participation at admission not only is associated with subsequent naturalization but also increases between admission and naturalization.

Data on IRCA (Section 245A)-legalized aliens provide a somewhat different picture; this is not surprising given the population (illegal aliens) and given that information about occupation pertains to the week before application for temporary residence under the legalization program. Only 2 percent are in the executive and professional category, and 28 percent are in the service occupations.

The 1990 Census reports that manufacturing, services, and construction absorb well over half (58 percent) of all employed Mexican immigrants 16 years or older. Another 17.5 percent work in retail trade. Only 13 percent are reported working in the "agriculture, forestry, and fisheries" sectors. This sector's share is lowest for naturalized citizens who entered the United States prior to 1980 (8.3 percent) and highest for noncitizens entering the United States between 1980 and 1989 (15.7 percent). The corresponding agricultural, forestry, and fisheries share for the employed U.S. workforce 16 years or older was 2.7 percent. In the LPS, the largest sector share by far for newly legalized migrants was in manufacturing (34 percent), followed by sales (24 percent) and services (20 percent). Agriculture claimed only 9 percent of IRCA (Section 245A)-legalized aliens from Mexico. The vast majority of agricultural-worker legalizations were through the Special Agricultural Worker (SAW) program, not under Section 245A. SAWs were not enumerated in the LPS.

Overall, the Census shows employed Mexican immigrants as more likely than the U.S. population as a whole to work in agriculture, forestry, and fisheries jobs; in construction (10.4 percent, compared with 6.2 percent); and in manufacturing (26.6 percent, compared with 17.7 percent). It shows them less likely than the U.S. workforce as a whole to be employed in services (20.6 percent, compared with 32.7 percent); transportation, communication, and other public utilities (3.3 percent, compared with 7.1 percent); finance, insurance, and real estate (2.1 percent, compared with 6.9 percent); and public administration (1 percent, compared with 4.8 percent). The employment shares in the other major sectors (retail and wholesale trade and mining) are similar for Mexican immigrants and the U.S. workforce at large.

Both the 1990 Census and the 1996 CPS data suggest a negative association between time in the United States and employment in agriculture—or else a high rate of return migration for agricultural workers from Mexico. In the CPS, the agriculture, forestry, and fisheries share is 18.6 percent for 1990-96 entrants, 12.3 percent for 1980-89 entrants, and 8.9 percent for pre-1980 entrants. It is highest for naturalized citizens in the 1990-96 group (41.6 percent), reflecting the effects

of the Special Agricultural Worker (SAW) legalization program. It is lowest for the pre-1980 naturalized group (3.2 percent). Employment shares in services are higher for older immigrant cohorts. For example, in the 1990 Census, the service sector absorbed 18.6 percent of 1980-89 entrants and 22.4 percent of pre-1980 entrants; in the CPS, 15.4 percent of 1990-96 entrants, 21.5 percent of 1980-89 entrants, and 28.7 percent of pre-1980 entrants 16 years or older who were employed worked in services. In most cases, employment profiles of "older" Mexican immigrant cohorts are more similar to the average U.S. profile than are employment profiles of "younger" cohorts.

Sector of employment differs sharply across sexes. The EMIF found that most returning female migrants (62.6 percent) worked in U.S. service jobs (33.9 percent in domestic services). 28.7 percent were in industrial jobs, and only 8.7 percent worked in agriculture. It is noteworthy that the industrial-job share for returning female migrants exceeds that for returning male migrants in the EMIF data.

Migrants originating from rural areas in Mexico are more likely to have worked in U.S. farm jobs (58 percent of returning migrants and 46.3 percent of north-bound migrants) than are migrants from urban areas (46.6 percent of returning migrants and 38.7 percent of north-bound migrants). Among returning migrants, both industrial and service-sector shares are higher for urban than for rural-origin migrants. Among north-bound migrants, however, industrial-sector and domestic-service employment are higher for rural than for urban-origin migrants.

Comparison of Migrants' Occupations in Mexico and the United States

International migration more often than not is associated with mobility across employment sectors. In fewer than one half (48 percent) of all cases does sector of work prior to migration coincide with sector of work in the United States (EMIF, returning migrants). Most agricultural workers in Mexico (67 percent) do not change sector of employment when they migrate to the United States, but most industrial workers and service workers do. For example, only 22.8 percent of service workers who migrated to the United States held service jobs there. However, 79.6 percent of domestic-service workers in Mexico did not change sector when they migrated. More than half of all industrial workers who migrate end up in U.S. agriculture, but only 27 percent of service workers do.

Earnings and Income

Data on earnings in 1995 from the 1996 CPS indicate that among persons 25 years and older reporting earnings or self-employment income, the mean and median for the Mexico-born were $15,612 and $13,020 versus $30,641 and $24,001 among

Source: INS Legalized Population Survey, INS (1992)

the native-born. Comparable figures from the 1990 Census are $14,138 and $12,776 among the Mexico-born and $24,408 and $22,365 among the native-born (all figures in current dollars). Thus, the ratio of median earnings among the Mexico-born to median earnings among the native-born declined from 57% in 1989 to 54% in 1995; the estimated decline using mean earnings is steeper, from 58% in 1989 to 51% in 1995. This relative decline in earnings may be due in part to changing legal-status and/or gender composition among the employed Mexico-born included in the Census and CPS.

Among the new legal immigrants of the FY 1996 cohort, average earnings among persons 25 years and older were $19,129 among men and $13,619 among women. Among those age 18 and older, the comparable figures are $18,694 and $14,798. This compares with average earnings for the entire U.S. working population aged 18 and above in 1995, based on Current Population Survey data (Current Population Reports, Consumer Income, Money Income in the United States, 1995, P60-193, Table 9) of $33,259 and $10,414, respectively. The Mexico-to-native earnings ratios are 0.56 among men and 1.4 among women. These ratios suggest not only that legal immigrants have higher earnings than unauthorized migrants but also that, while legal-immigrant men display the classical pattern of lower earnings at entry, possibly reflecting their relative youth and lack of U.S. experience compared to the native-born, Mexico-born legal-immigrant women out-earn their native-born counterparts, on average.

Data limitations make it difficult to directly ascertain differences in earnings between legal and undocumented Mexican migrants. Insight can be gained, however, from the UC-EDD farmworker data and from surveys including formerly unauthorized migrants, such as the Legalized Alien Population Surveys and the New Immigrant Survey Pilot Study.

Research utilizing UC-EDD farmworker data found that undocumented migrants were significantly less likely than otherwise comparable legal workers to hold relatively skilled, machine operator and foreman jobs, and those who did hold skilled jobs had significantly lower earnings than legal workers in those jobs. Estimated weekly earnings for legal workers were $236 in relatively skilled

("primary") jobs and $185 in less skilled ("secondary") jobs. Moreover, weekly earnings for undocumented workers were not significantly different ($176-$177) in the two types of jobs.

The first round of the Legalized Population Survey collected information about earnings of the legalized persons (persons approved for the first-step legal temporary resident status) at the time they applied for legal temporary residence (i.e., between May 1987 and May 1988). Median prelegalization earnings (1987/1988) among the LPS newly legalized migrants were $8,435, a figure substantially lower than the median earnings of Mexico-born in the 1990 Census, $12,776, which includes both unauthorized and legal migrants. If those unauthorized migrants who were not eligible for legalization (e.g., newcomers) or who chose not to apply or who applied but were denied legalization have lower earnings than the IRCA legalized aliens, then the difference between with the average earnings of unauthorized and legal migrants is even larger.

The NIS Pilot Study includes information concerning entry without inspection at the first trip to the United States and also concerning whether adjustment to permanent resident status was from an EWI status. Accordingly, sample members can be classified into two groups, those with some EWI experience and those with none. Because full migration histories were not collected in the Pilot Study, the latter group includes individuals who may have EWI experience during an intermediate trip. Thus, the measure is conservative, and any differences between the two groups understate the true differences between persons with and without EWI experience. Among persons aged 18 and older, average male earnings for the group without EWI experience was $21,867 and for the formerly unauthorized, $17,709. The comparable figures among women were $12,393 and $17,461, respectively. Thus, while, as expected, among men average earnings is lower for the formerly unauthorized, the opposite is true for women. Moreover, U.S. earnings do not differ appreciably between the sexes among the formerly illegal, while among immigrants with no EWI experience, a large gender gap is observed (a ratio of female to male earnings of 57 percent). In a nutshell and putting it roughly, the formerly illegal of both sexes earn the same, and this amount lies halfway between the earnings of legal women and legal men. These results suggest that both selection mechanisms and earnings patterns by legal status may be gender-specific. Future research on this topic is warranted.

Turning to income, according to the U.S. 1990 Census, the mean household income among households with a Mexico-born head was $27,122, or about 70 percent of the U.S. mean of $38,453. Median household incomes for the two groups were $21,926 and $30,056, respectively.

Households with a Mexico-born head are much more likely than all U.S. households to be found at the bottom of the income distribution, and they are

much less likely to be found in the highest income ranks. Twenty-seven percent of all Mexican-headed households had incomes below the federal poverty line in 1990, compared with 13 percent of all U.S. households. The shares of Mexican migrant households are higher than those of all U.S. households in the lowest 5 income ranges reported in Table 1, Volume 2, page 750. They are lower in all of the remaining (upper) income ranges.

The shares of households in the lowest income groups are lower for the pre-1980 cohorts than for the 1980-89 cohort, and the shares in the highest income groups are higher for the "older" cohorts. This suggests that there are some economic returns to U.S. experience and/or that there is a positive selectivity of settlement on earnings—that is, low-income individuals and families are more likely eventually to return to Mexico. In contrast to migrant year-of-entry cohorts, shares of households in different income groups are remarkably similar between the two migrant-status groups.

The CPS data reveal a concentration of new (1990-96) migrant households at bottom of the income spectrum. The share of the 1990-96 household cohort with incomes less than $5,000 is 10.6 percent, double the shares of the 1980-89 and pre-1980 groups. The shares of households in the $5,000-$9,999 and $10,000-$14,999 income groups are also high for the 1990-96 group.

Both average and median incomes are higher for U.S. households in the 1996 CPS than in the 1990 Census, but the opposite is the case for Mexican-migrant households. The mean for all U.S. households is $38,453 in the Census and $44,938 in the CPS. The mean for Mexican-migrant households is $27,122 in the Census and $26,481 in the CPS. The U.S. median household income is $30,056 in the Census and $34,076 in the CPS, while that of Mexican-migrant households is $21,926 in the Census and $20,601 in the CPS. Thus, even though the real increase, after adjusting for inflation, may be smaller for the total U.S. population, it is clear that households headed by Mexico-born persons experienced a decrease in income. Of course, this may reflect changing household composition (e.g., fewer adults) or changing visa-status composition (e.g., a larger proportion of men working without permission).

The hypothesis that unauthorized migrants have lower household income than legal immigrants can be examined by comparing migrants legalized under IRCA Section 245A to the entire population in the Census or CPS. The first round of the Legalized Population Survey also collected information on family income of the legalized persons. Average prelegalization family income (including income contributions by all family members in the household) was $17,551 (median income: $14,875), substantially less than the comparable figures in the 1990 Census (average, $27,122; median, $21,926), which include both unauthorized as well as legal migrants (U.S. INS 1992). As discussed above with respect to earnings, if those unauthorized migrants who were not eligible for legalization

(e.g., newcomers) or who chose not to apply or who applied but were denied legalization have lower average family income than the IRCA legalized aliens, then the difference between with the family incomes of unauthorized and legal migrants is even larger.

Conclusions

Our findings indicate that Mexico-to-U.S. migrants, unlike international migrants from most other countries, have tended to be selected from the middle-to-lower ranges of the socioeconomic hierarchy, in a selection process originating with the recruitment of low-skilled Mexican workers by U.S. employers and facilitated by the long and historically porous border between Mexico and the United States, which puts U.S. labor markets within reach of individuals with limited financial resources in Mexico; by the expanding demand for low-skilled immigrant workers in the United States; and by extensive "migration networks" connecting families throughout Mexico with low-skill U.S. jobs.

Characteristics of Mexican migrants are not static, however; they change over time. Some of these changes appear to be long term. For example, there is evidence that schooling levels of Mexican migrants are increasing over time, that migrants' origins and destinations are increasingly urban, and, overall, that characteristics of Mexican migrants may be increasingly heterogeneous. These partly reflect changes in the population at large in Mexico from which migrants are drawn but may also reflect long-term changes in the selectivity of migration, including the influence of migration networks. Other changes are short-term, cyclical (i.e., related to recessions and expansions in the two countries) or discrete, resulting from exogenous shocks like droughts. Changing labor market conditions in the United States are instrumental in shaping migration flows and observed characteristics of migrants, given the importance of work as an objective of migration. Still others may be law- or policy-induced, for example, the large-scale legalization of migrants under IRCA. There are some indications that migration is becoming less selective over time, as shown in the Michoacán and Mexico migration surveys. This could be due to the operation of migration networks, buttressed by the family reunification provisions of US immigration law, which reduce the costs of migration for an individual prospective migrant.

The low average skill level of Mexico-to-U.S. migrants obscures the participation of highly educated individuals in migration. Even though the number of highly skilled Mexican migrants is small relative both to the number of skilled people in the United States and to the total Mexico-to-U.S. migrant flow, it is significant relative to the skilled population in Mexico. The presence of highly educated individuals among Mexico-born persons enumerated in the Census may reflect in part Mexicans

pursuing higher education in the United States. The subsequent migratory behavior of these highly educated individuals is of obvious importance to the two countries and deserving of future research.

We have focused on the characteristics of migrants, but full comprehension of the migration phenomenon must consider the migrants' legacy for their families and for their places of origin and destination. Mexico and the United States are deeply intertwined. Many Mexicans have American relatives and ancestors, and many Americans have Mexican relatives and ancestors. This is particularly visible in border areas but extends geographically following historical migratory flows. This intertwining is found across the broadest socioeconomic spectrum of each country and reaches into artistic, literary, scientific, and governmental circles. The migrants' legacy includes migrants' children, wherever they may settle, but it also includes the enlarged perspectives of individuals in transnational families and societies. Studying the migrants' legacies would seem to be an important task for future research in both countries.

Of course, perceived characteristics often differ sharply from the actual characteristics of a given population (see Volume 2, pages 819 to 867). Such discrepancies may be endemic to migration, given that migrants are often viewed very differently in the origin and destination countries, as well as by different groups within countries. The challenge is to distinguish between actual characteristics, as defined and measured through scientific procedures, and perceived characteristics that may or may not have empirical foundation.

Because migration is dynamic and conditions in both the United State and Mexico change, understanding Mexican migration to the United States requires continual monitoring. We recommend establishing a bilateral program of longitudinal research on successive cohorts of new migrants. This binational study is an important first step in that direction.

Notes

NOTES: Subsets identified in the data are denoted by closed rectangles. Missing rectangle denotes the absence of persons in the data set currently in that legal status. The set of deportable migrants includes legal nonimmigrants who violate the terms of their visa and entrants without inspection. The "other Mexican household surveys" discussed in the text resemble ENADID in their information on legal status.

1. At the inception of this study, our intention was to encompass not only Mexicans in the United States but also Americans in Mexico. Unfortunately, the study of Americans in Mexico is seriously neglected by scholars in both countries. Of course, there is a large American presence in Mexico—ranging from American clubs to a network of American

schools—as American visitors to Mexico quickly learn. According to data collected by the U.S. Department of State, Mexico is the leading country of residence for Americans abroad, attracting 20 percent of the total: 522,274 civilian Americans (excluding employees of the U.S. government and family members of U.S. government and military personnel) resided in Mexico as of May 1, 1993. The second largest contingent is found in Canada—335,490, or 13 percent of the total.

The ENADID data set described includes U.S.-born individuals residing in Mexico (including U.S.-born children of Mexican migrants). These data, in particular, merit further study.

2. The ENADID represents the most important and complete macro-social treatment of demographic behavior in Mexico. It integrates the three aspects of demographic dynamics (fertility, mortality, and migration). It is the first national-level study, covering practically every zone in the country. For purposes of our research, it encompasses the following units of analysis: dwellings, domestic and foreign members of these dwellings, habitual residents of these dwellings, and persons from these dwellings who left to live in another country between 1987 and the date of the survey (additional information is available in Volume 2, pages 769 to 778).

3. For these few characteristics—sex, age, birthplace by state—individuals who recently have migrated to the United States are very similar to return migrants.

4. See the methodological appendix elaborated by the National Population Council (Consejo Nacional de Población—CONAPO).

5. Massey, Goldring, and Durand (1994) propose an index of community "migration prevalence" as a basis for comparing communities that are apparently at different stages of the migration process. For a given community at a given point in time, international "migration prevalence" is defined as the number of people with international migratory experience divided by the total number of people alive.

6. Naturalization appears to be seriously overstated in U.S. Census and CPS data—e.g., over 100,000 Mexico-born persons in the 1990 Census report that they entered in 1985-1990 and that they are naturalized—even taking into account the fact that the Census question on period of entry refers to the "latest year he/she came to stay," so that admission to permanent residence might predate reported period of entry and be consistent with the reported naturalization. For comprehensive analysis of the measurement of naturalization in Census and CPS data, see Passel and Clark (1997).

7. As pointed out by diverse sources, this out-migration had its origins in the recruitment of workers by North American employers for jobs in agriculture and railroad construction.

8. See, for example, Samora (1971), the findings of the ENEFNEU (1978-79) study reported in Zazueta and Corona (1979), and the findings of ETIDEU (1984) in CONAPO (1986).

9. Colima is included because of its geographic location and because, although in relation to the total migrant flow its weight is small, migrants represent 5.7 percent of its resident population.

10. South Baja California's share is minimal, with only 0.2 percent of all migrants coming from that region (0.95 percent of the region's resident population).

11. In the Samora study, 84% of the sample originated from rural areas. In the ENEFNEU this percentage was lower—69.8%. Nevertheless, it was greater than that observed for the total Mexican population in 1978 (53 percent).

12. It is possible that this predominance is related to age (deported migrants are younger) and the demographic growth of this region, in which the urban population is predominant. It also may be affected by a relative importance of migration networks in rural versus urban communities, with the result that urban-origin migrants find themselves less protected by these networks when they enter the United States to work.

13. According to the U.S. Census, presented by Gamio (1930).

14. It is likely that the large weight for the northern states is due to the rising demand there for low-skilled workers, relatively high wages for these workers, and perhaps also to the fact that, in the border states, many of the Mexicans interviewed no longer maintained economic ties with families in Mexico. Unfortunately, this indicator of migrant populations is very sensitive to remittance behavior.

15. The ENEFNEU was carried out by the Centro Nacional de Información y Estadísticas del Trabajo (CENIET) of the Secretaría del Trabajo y Previsión Social, between December 1978 and January 1979. Its sample size is 62,500 housing units in 115 localities, randomly selected. It gathered information on approximately 300,000 individuals (CENIET, 1982: 57).

16 INS data also suggest that immigrants who choose to live in the Southwest are less likely to subsequently naturalize than their counterparts who settle elsewhere (Table 2).

17. It is likely that the different weights of females in the ENEFNEU is due to this survey's inclusion of migrants with and without documents. It is common for women to migrate with documents.

18. The differences result from both the type of data and the ways in which these data were collected. The EMIF only captures labor migrants, while the universe for the ENADID, in theory at least, is the total Mexican population. Moreover, the fact that the EMIF is carried out at the border, at the moment of the border crossing, reduces the share of females: A number of micro-regional studies have shown that women normally migrate only when they have documents, and these make it possible to travel directly between places of origin and destinations in the United States (i.e., by air). Finally, stays in the United States typically are longer for women than for men. This reduces the probability that women will be picked up in surveys of circular migrants at the border.

19. Information on sex is not available for the immigrant cohorts of Fiscal Years 1980 and 1981.

20. Sex-specific counts of spouses of U.S. citizens were published in the INS annual reports until 1979. The figures for 1982 and 1994 are based on the microdata public-use files, and the figure for 1985 is estimated from the GAO data.

21. In the total registered population the difference is greater: 34.2 for women, 31.8 for men.

22. In the total population, average age is 34.9 for women and 32.8 for men.

23. In the ETIDEU the average is the same overall and 4.6 for women.

24. Information on average schooling from the EMIF was provided by Dr. Jorge Santibáñez of the COLEF.

25. It is possible that many of those with high schooling levels worked simply as research or teaching assistants during their post-graduate studies.

26 Difficulties in comparing Census and CPS findings make it inadvisable to infer increases or decreases in schooling levels between 1990 and 1996 from these comparisons.

27 Respondents classified as having EWI experience met at least one of two criteria: (i) their first trip to the United States was without legal documents, or (ii) adjustment to permanent residence was from an EWI status. Because the NIS Pilot Study did not collect complete migration histories, the measure of EWI experience yields an underestimate, and hence measured differences between the two subgroups understate the true differences.

28. It should be pointed out that this is based on small samples: 9,687 north-bound migrants and 2,972 voluntarily returning migrants. Among deported migrants the number is much larger: 25,588.

29. The ENADID does not provide information on migrants' type of work activity in the United States.

30. There is some evidence of increasing diversification of employment for Mexican migrants by 1920, particularly in the eastern and midwestern parts of the United States; see Santibáñez, 1930 and Gamio, 1930 y 1969. However, there was a reconcentration in agriculture under the Bracero Program (Fonseca, 1986).

Factors that Influence Migration

Agustín Escobar Latapí, Philip Martin, Gustavo López Castro & Katharine Donato

Executive Summary

This report examines the factors that cause people to cross the Mexican-U.S. border and work temporarily or settle outside their country of citizenship, and assesses the factors that sustain such migration over time. Most of the cross-border labor and settlement migration involves Mexicans moving to the U.S.; this report therefore focuses on factors that influence and sustain Mexico-U.S. migration.[1]

In absolute terms, the United States is the world's major country of immigration, and Mexico is the world's major country of emigration. The U.S. accepted 916,000 legal immigrants in FY96, more than any other country, plus 275,000 unauthorized settlers. About 165,000 of these legal U.S. immigrants were Mexican nationals; if another 125,000 unauthorized settlers were Mexican nationals, then Mexican immigration to the U.S. in FY96 exceeded total immigration to Canada in 1996, which was about 225,000, and was nine times the immigration of 100,000 foreigners to Australia.

The best estimates suggest that there were 7 million to 7.3 million Mexican-born residents in the U.S. in 1996, including 4.7 to 4.9 Mexican-born residents

authorized to be in the U.S., and 2.3 to 2.4 million unauthorized Mexican-born residents.[2] The number of legal and unauthorized Mexican-born residents living in the U.S. is increasing by 277,000 to 340,000 per year.[3]

The U.S. labor market is proportionately more important to Mexican workers than Mexican workers are to the U.S. labor market. Some 4 million to 5 million Mexican nationals, equivalent to one-eighth of Mexico's labor force of 37 million,[4] are employed in the U.S. in a typical year. However, even if there are 5 million Mexican-born workers in the U.S. labor force, they would represent less than 4 percent of the average 130 million persons employed in the U.S.

Mexico to United States migration has a long history, and has become one of the most important linkages between the two most populous countries in North America, affecting employment patterns, demographic trends, regional dynamics, and politics in both countries. "Go north for opportunity" is an idea deeply embedded in Mexican youth, especially in the rural areas of west central Mexico. Closer economic integration between the U.S. and Mexico, including more trade and investment, is interacting with migration patterns and altering them in significant ways in the 1990s.

Findings

We group the factors that sustain Mexico-U.S. migration into three broad categories; demand-pull factors in the U.S., supply-push factors in Mexico, and network factors that bridge the border. Our analysis leads to a simple conclusion; the migration of persons from Mexico to the U.S. is a dynamic process. What began largely as the U.S.-approved or U.S.-tolerated recruitment of Mexican workers for mining, railroad, and seasonal U.S. farm jobs a century ago has become a far more complex migration relationship that is moving rural Mexicans into traditional and nontraditional industries, occupations, and areas of the U.S.

Our report is based on three key findings:

- First, the origins of Mexico-U.S. migration lie largely inside the United States—Mexican workers were recruited earlier in the 20th century for U.S. farm jobs, creating linkages between jobs in U.S. agriculture and workers in particular Mexican communities.

  Today cross-border networks of relatives, friends, and labor brokers and recruiters link an expanding list of U.S. industries, occupations, and areas to a lengthening list of Mexican communities that send migrants to the U.S. While in Mexico, residents of these Mexican communities often have better information about the availability of certain types of U.S. jobs than do local U.S. residents.

The U.S. labor markets in which Mexican migrants are finding U.S. jobs are changing, and may change even more as a result of technological and trade trends and as welfare reform adds to the supply of low-skilled U.S. workers. First, most Mexican workers are employed outside of U.S. agriculture: about 80 percent of Mexican-born workers in the U.S. hold nonfarm jobs.

Second, the demand side of U.S. labor markets is changing, as U.S. employers adjust to higher minimum wages and more global competition. On the supply side, high immigration since the 1980s and legalization in 1987-88 permitted Mexican-born workers to become significant components of the U.S. food processing, construction, service, and manufacturing labor forces throughout the U.S. Welfare reforms and continued immigration promise to continue to add unskilled workers to the labor supply in the 1990s.

Third, it is not clear whether the U.S. labor market will continue to evolve in ways that absorb large numbers of Mexican immigrant workers. On the one hand, the U.S. unemployment rate dropped to its lowest levels in 25 years in 1997, and there are reports of labor shortages, especially in low-wage labor markets in areas with unemployment rates of less than 2 percent, such as the midwest. U.S. job growth is very rapid: between January 1, 1994 and June 1, 1997, the U.S. economy added about 8 million jobs. With Mexican-born workers spreading throughout the U.S. in a period of rapid job growth and low employment, networks that bridge the border may be strengthened, increasing the demand for immigrant workers, and making Mexican immigrant workers a permanent feature of more U.S. industries and areas.

On the other hand, the U.S. is committed to stepped up controls at the border and in the interior, to moving 2 million to 3 million adult welfare recipients into jobs, and to creating jobs for the rapidly growing domestic labor force. The 140 million strong U.S. labor force, which usually expands by about 1 percent per year or 1.4 million per year, has been expanding about twice as fast, due to immigration, welfare recipients moving off the rolls, more older men working, and an increase in the percentage of working-age women seeking jobs. In 1997, over 67 percent of the U.S. population 16 and older was in the labor force, a record percentage of adults employed or looking for work.

It is hard to project the evolution of labor markets that immigrants traditionally enter. In many areas of the U.S., immigrant workers, fears of

labor shortages and high welfare caseloads go together. For example, in the San Joaquin Valley of California, about 85 percent of the 400,000 individuals who work as farm workers sometime during a typical year are immigrants, including 100,000 or more unauthorized migrants. Farmers fearful of labor shortages are calling for modifications of the H-2A program to make it easier to obtain temporary foreign farm workers. At the same time, 25 percent of the 761,000 residents of Fresno county are receiving some form of welfare assistance, and the unemployment rate in Fresno is over 10 percent for most months.

One scenario is that immigrant labor markets will segment, with some U.S. employers reacting to low unemployment and welfare reforms that limit assistance for immigrants by offering English and other services to help their immigrant employees to become naturalized U.S. citizens. Other U.S. employers, such farm labor contractors, may go further into the underground economy to avoid labor law and immigration enforcement, hiring recently-arrived immigrants. Further segmentation of immigrant labor markets could mean that networks may become more important, with the ability to get into the upper segment of the unskilled immigrant labor market the key to economic mobility in the U.S.

- Second, the factors that initiate migration flows are not necessarily the only ones that sustain Mexico-U.S. migration. We find that there is still a demand-pull for Mexican workers in the low-unemployment U.S. labor market, in the sense that most recently-arrived legal and unauthorized Mexican migrants can find jobs in high turnover farm, manufacturing, and service jobs, both in areas where Mexican-born workers have traditionally played important roles, as in southwestern agriculture, and in new industries in the midwest, the southeast, and east coast, including construction, meatpacking, and services. In some cases, including poultry and meat packing, private labor brokers play an active role in moving Mexican workers to jobs in the midwest and southeast.

  Supply-push factors in Mexico play a role as fundamental as the availability of U.S. jobs in sustaining Mexico-U.S. migration. Supply-push factors seem to have become more important since the mid-1980s as a result of recurring Mexican economic crises, peso devaluations, and Mexican policies aimed at economic modernization, such as the privatization of government-owned industries that resulted in layoffs and the restructuring of rural Mexico that made small-scale farming less profitable.

This means that Mexicans migrate to the U.S. (1) within well-established networks as well as (2) through new networks that are developing to move migrants to the U.S. from regions without a tradition of Mexico-U.S. migration, such as from Mexican cities and southern Mexican states. Friends and relatives established in the U.S. often provide financing, advice, shelter and jobs to newly-arrived migrants. Settled family members use U.S. family unification policies to have spouses and children join them, and eventually secure legal immigrant status.

The U.S. border enforcement strategies begun in 1994, 1995, 1996, and 1997 under the Hold-the-Line, Gatekeeper, Safeguard, and Rio Grande labels are affecting migration patterns, but not preventing unauthorized entry. First, we find that most (73 percent) of Mexicans attempting unauthorized entry into the U.S. hire polleros or *coyotes* to help them cross the border, and that migrants with the fewest network links to bridge the border are most likely to rely on the smugglers who operate as border-only businesses. The increased use of coyotes generally, and of border businesses in particular, helps to explain why most migrants attempting unauthorized entry succeed (70 percent or more) despite significantly more U.S. Border Patrol agents and technology on the border.

Second, we find that smuggling has achieved enough regularity to become an established business with three segments; local agents, local and border smugglers, and border-only smuggling businesses, each with a menu of prices and services. After U.S. border control operations were stepped up in 1994, more migrants turned to coyotes, whose services became more diversified. Thus, unauthorized migrants have several packages of services available, and several options to pay for the cost of illegally entering the U.S., including working in a coyote-provided or coyote-arranged job in the U.S. to repay smuggling costs.[5]

In some areas of west central Mexico, survey data suggest that migration to the U.S. has become a way of life. Based on migration histories collected in 39 communities in traditional emigration areas, we estimate that, by the time they are 40, most of the men in these communities make at least one trip to the U.S. Based on a model that predicts migration to the U.S. on the basis of age and community characteristics, it appears that, in some communities, the probability that a young man will make a first trip to the U.S. increased after 1992.

- Third, we find that there is reason to believe that currently high levels of Mexico-U.S. migration may represent a hump or peak in the volume of

Mexico-U.S. migration. Within the next decade, we think that demographic and economic factors within Mexico are likely to reduce emigration pressures.

One long-term supply-push factor explaining the mid-1990s migration hump, and the eventual decline in emigration pressure, is demography: the number of new job entrants entering the labor force in Mexico has been very high, but will decline. In 1997, the number of new labor force entrants in Mexico is expected to be 970,000. However, the declining birthrate since 1970,[6] when Mexican women averaged seven children each, means that the growth in the labor force is slowing, and is projected to drop to 500,000 to 550,000 per year by 2010.

Mexico adopted an ambitious restructuring and privatization program in the 1990s that promises to increase economic efficiency and job growth in the medium to long term, but displaces workers in the short term. If Mexico maintains market-driven economic policies, the International Monetary Fund projects 5 percent annual economic growth, and 2.5 percent employment growth, for 1997 and thereafter.

Given this 2 to 1 ratio between real GDP growth and employment growth, an average 5 percent economic and 2.5 percent job growth per year would lead to the creation of 750,000 new jobs each year, based on 30 million employers and wage and salary employees.[7] The actual ratio of economic growth to employment growth in recent years has been a more favorable 1.35; this was the ratio of economic growth to labor force growth for the period 1988 to 1995.[8] Using a 1.35 ratio, 5 percent annual GDP growth would generate 3.7 percent job growth, or 1.1 million new jobs each year.[9]

Sustained economic growth plus the declining number of new job seekers means that, early in the 21st century, Mexico could be creating enough net new jobs to absorb new labor force entrants. Mexico could then begin to catch up on job creation for currently unemployed and underemployed workers, those displaced from agriculture and other industries, and nonworking women who rejoin the labor force. We emphasize that medium-to-long term demographic and economic indicators suggest that supply-push emigration pressure should decline from current levels because it is easy to focus on recent events that point to increases in emigration pressure, including the peso devaluation and economic crisis of 1995, and the uneven recovery from recession.

This longer term perspective emphasizes changing structural factors in Mexico that could reduce Mexico-U.S. migration. The demographic factors are real, and their effect on reducing emigration pressure could be magnified if, e.g., more young people stay longer in school. The economic factors are less certain; Mexico has experienced uneven economic growth over the past several decades, and could experience recessions and crises again.

Other changes in Mexico may also reduce emigration pressure. Migration networks are best established in rural areas with long traditions of sending young men to the U.S. As the number of persons employed in Mexican agriculture shrinks, and some ex-farmers are absorbed in Mexico's service economy, there should be fewer Mexicans with strong network connections ready to migrate to the U.S.

The Mexican economy is stabilizing and growing; the economy grew by almost 9 percent in the second quarter of 1997. Mexico's economy grew by 5.1 percent in 1996, after shrinking by 6.2 percent in 1995, and is projected to grow by 4.5 percent to 5.1 percent in 1997.

The number of permanent workers enrolled in the Mexican Institute for Social Security (IMSS), which is considered a good guide to the number of formal sector jobs in the private sector, rose by a record 661,024 in 1996 to 9,163,459, an expansion characterized by the OECD as "strong job creation in the 'formal' economy" (OECD Economic Outlook 61, June 1997, 98). Job growth continued in 1997; some 282,782 permanent workers were enrolled between January and April 1997, bringing the total to 9,446,241 at the end of April 1997, including 103,000 additions in April. Of the permanent workers enrolled in IMSS, 40 percent were in manufacturing (377,000 new IMSS jobs in 1996), 36 percent in services (166,000), 19 percent in trade (103,000), and five percent in agriculture (16,000).

However, interest rates remain high, the peso may be overvalued, and the recovery is unequal, accentuating inequality. Mexicans linked to the world economy via exports of manufactured goods are doing much better than those operating only in the domestic economy, such as in construction and small-scale agriculture.[10] Inequality has increased since 1984; according to the 1997 UNDP Human Development Report, the richest Mexican person has assets equivalent to the incomes of the poorest 17 million Mexicans.

Thinking About Mexico-U.S. Migration

We find it useful to think of migration processes between Mexico and the U.S. as analogous to a river that creates a delta en route to the ocean. When the Bracero Program was in operation, the flow of Mexicans north was largely confined to the channel created by legal recruitment. Blocking that channel by abolishing the Bracero Program in 1964 thus stopped the migration flow temporarily. The migration soon resumed, however, with a myriad of small streams the vehicle for Mexicans migrating north.

Visualizing Mexico-U.S. migration as having evolved from a narrow channel to rivulets meandering through a delta provides insights into a complex and dynamic migration process:

1. If the underlying demand-pull, supply-push, and network factors change in strength and relative importance, policies designed to deal with just one factor at one level of migration may lose their effectiveness over time. For example, U.S. policies that were based on the assumption that the major factor sustaining Mexico-U.S. migration was legally-authorized demand-pull U.S. employer recruitment became less effective in the 1970s and 1980s as the key factors sustaining migration shifted to informal U.S. employer recruitment and supply-push and network forces. In such circumstances, simply stopping legally-authorized foreign worker recruitment did not stop migration.

2. Both the U.S. and Mexico took steps over the past decade that reinforced the network and supply-push factors that encourage Mexicans to go north for opportunity:

   — The U.S. legalized the presence of over 2 million Mexicans in 1987-88, including 1 million farm workers. The 1 million legalized Special Agricultural Workers who were Mexican meant that the equivalent of one-sixth of the adult men in rural Mexico gained the right to settle in the U.S. and petition to have their families join them. One U.S. government commission concluded that the SAW farm worker legalization program promoted unauthorized Mexico-U.S. migration by giving the impression that doing unauthorized farm work in the U.S. was a way to become a legal immigrant (Commission on Agricultural Workers, 1992).

   — Mexico in the early 1990s changed its economic policies in a manner that may compress into a decade or less what would otherwise have been a slower shrinking of employment in agriculture. Mexico eliminated most input subsidies and price guarantees in agriculture,

switched to direct payments to farmers, and eased trade restrictions, signaling the eventual shrinking of the production of many commodities, notably corn, that today absorb a great deal of labor, but in which Mexico does not have a comparative advantage.

— Extensive networks of family, community, and private agents have developed to assist Mexicans wishing to migrate legally and illegally to the U.S., including a variety of advisors, smugglers, and transportation agents. The migration infrastructure has become very sophisticated, so that migrants have choices in deciding who will help them to cross the border, how to finance the trip, and in finding U.S. employment.

3. It should be kept in mind that some of the factors that today are producing high levels of Mexico-U.S. migration should abate over the next 5 to 15 years.

— First, Mexico's population growth has slowed, which promises fewer new labor force entrants in the years ahead.

— Second, workers can be displaced from agriculture only once. Thus, after the Mexican farm labor force has been reduced from 25 percent of all workers in the mid-1990s to 12 to 15 percent by 2015, supply-push emigration pressures from the areas that have some of the best network connections to the U.S. should diminish.

— Third, the destabilizing impacts of Mexican institutional and market reforms should run their course. If economic growth is sustained at current and projected levels, jobs and upward pressure on wages should encourage many potential migrants to remain in Mexico.

— Fourth, the U.S. labor market is expected to absorb a large number of unskilled workers over the next few years, as the normal complement of new job seekers are joined by persons removed from welfare rolls. This increased supply of U.S. workers, as well as more border and interior enforcement, may reduce the availability of jobs for newly-arrived Mexican workers.

Policy Recommendations

Bearing in mind our key findings:

- The catalyst for much of today's unauthorized Mexican migration for U.S. employment lies in the U.S., but solutions are to be found in both countries.

- The same tendencies that currently seem to be increasing and diversifying Mexico-U.S. migration flows may be dampened starting in the next 5 to 15 years, thus reducing Mexico-U.S. migration.
- There is no magic bullet solution such as a guest worker program to deal with unwanted Mexico-U.S. migration, we make three policy recommendations:

1. The social and economic policies of the U.S. affect Mexico-U.S. migration patterns, just as Mexican policies affect emigration. Repeatedly, the U.S. or Mexico have been surprised by the other's changes in policies that affect migration patterns. To prevent unanticipated migration flows, a consultative mechanism should be established so that the U.S. and Mexico make each other aware of policy decisions that are likely to affect migration patterns.

   This recommendation echoes that of the U.S. Commission for the Study of International Migration and Cooperative Economic Development in 1990, which called for migration impact statements within the U.S. government to prevent the shock of unanticipated migration like that, for example, that arose in the Caribbean after the U.S. government increased its support of U.S. sugar producers by reducing sugar imports.

   We recommend that a U.S.-Mexico group be established to develop migration impact statements in both countries, and that these statements be discussed during annual U.S.-Mexican presidential meetings so that the migration issues discussed at these meetings include some mid-to-long-range perspectives. This approach may help to reduce bilateral tensions over migration issues, and may lead to a framework for bilateral migration management.

2. We recommend that both the U.S. and Mexico focus on the major U.S. attraction for migrants, jobs and higher earnings, that more be done inside the U.S. to prevent the employment of unauthorized workers, and that Mexico seek to avoid the creation of new migration networks from areas of Mexico that have traditionally not sent migrants to the U.S. Recognition of the different degrees of dependence on immigration and emigration inside each country could lead to migration management policies tailored to each major immigration/emigration area. For example, the U.S. may want to rethink its policy of requiring the INS to search open fields for unauthorized workers, since surveys suggest that the percentage of unauthorized workers has climbed steadily in the 1990s. Mexico may want to

prevent a culture of migration from developing in areas that are just beginning to see an outflow to the U.S.

3. At this time, we are not prepared to recommend a bilateral U.S.-Mexico foreign worker program, although we are mindful of the recommendations of many in both the U.S. and Mexico that a new program with Mexico be started.[11]

   There are three major reasons why we are not recommending a program at this time. First, there are few "certifiable" labor shortages in the U.S. industries, occupations, and areas in which Mexican and other non-immigrant workers are employed. In some of these immigrant labor markets, real wages have declined, and work-related benefits have disappeared. Certification of employer need for the foreign workers currently employed is often the subject of litigation, and the use of legal non-immigrant workers in these jobs may become more contentious as welfare reform augments the supply of unskilled U.S. workers. There may also be less seasonality in many of the labor markets in which Mexican-born workers are employed than is assumed, making it difficult to expect or enforce the worker rotation implicit in non-immigrant guest worker programs.

   Second, U.S.-sanctioned *bracero* recruitment in the 1950s is widely considered to have oriented many Mexican workers toward the U.S. labor market instead of toward local jobs and development. Today, when Mexico is modernizing its economy and promoting export-oriented economic development, a Bracero Program may make investors reluctant to invest in areas from which migrants leave for the U.S., thus reinforcing their dependence on emigration. If guest workers were to come from nontraditional migration areas, new migration streams may be set in motion.

   Third, there is as yet no convincing evidence that U.S. border and interior control efforts have reduced unauthorized Mexico-U.S. migration, so that opening a legal channel for Mexican temporary workers would probably add to rather than substitute for unauthorized workers, depressing conditions for legal Mexican-born workers in the U.S. labor market.

   Perceptions in the U.S. and Mexico are often very different about the ability of a temporary worker program to serve as a remedy for unauthorized Mexico-U.S. migration, so we recommend that the U.S. and Mexico study the guest worker idea very carefully to dispel myths

about what might be involved. We think that such a study would puncture the notion that U.S. employers, worker advocates and the U.S. government could easily reach agreement on the details of a program with the Mexican government and Mexican workers.

The demands from each side make the gaps clear. Mexico would like any bilateral guestworker to be large enough to substitute legal for unauthorized labor migration, to ensure that both Mexican workers and U.S. employers participate in the program, and to protect the legal and work place rights of legal migrant workers. A program agreed to by the U.S. would aim to admit only workers needed to fill legitimate labor shortages, and to ensure that foreign workers do not adversely affect similar U.S. workers. In addition, the U.S. would require that migrant workers remain legal nonimmigrant workers, and leave when their terms of employment end.[12]

Report Outline

The findings and policy implications summarized above are based on our review of the research that has accumulated on Mexico-U.S. migration as well as empirical work commissioned for the binational study. Some of our findings are based on the community studies that have been done in Mexico, and some on the U.S. communities where the Mexican migrants settle. Many of the community studies, including those based on the Mexican Migration Project (MMP) data, concluded that non-economic factors have become as important as economic factors in motivating and sustaining Mexico-U.S. migration.

Our report has five sections. The following section lays out our demand-pull, supply-push, and network framework for examining the evolution of Mexico-U.S. migration. We then turn to a review of case and community studies of Mexico-U.S. migration, demonstrating that the major motivators of Mexico-U.S. migration have shifted from demand-pull recruitment to a more complex situation in which supply-push factors increase the number of migrants, in part because of mature and evolving networks. We also present our re-analysis of Mexican Migration Project data on 30 Mexican communities that send migrants to the U.S.

The third section introduces the results of recent case studies conducted for the Binational Study. We then turn to key informant and poll data on the current migration peak or hump, explaining why Mexico-U.S. migration seems to be higher in the mid-1990s than in the immediate past. We discuss the factors that might reduce migration pressures.

The final section restates our conclusions, and Volume 3, pages 869 to 1000, includes detailed analyses of several issues mentioned in the report.

Demand-Pull, Supply-Push and Networks

There are as many reasons for migration as there are migrants. However, most individuals who cross national borders for employment and/or settlement do so for one of two major reasons—economic or non-economic. The factors that lead individuals to migrate, in turn, are motivated and sustained by three major types of influences—demand-pull, supply-push, and network and other factors.

The result is a 2x3 matrix summarizing why people migrate, and the factors that sustain migration flows. Specific kinds of migrants are found in each cell, and individual migrants may fit into more than one cell. For example, economic migrants may require all three influences to decide to move across borders for employment—a supply-push reason for seeking employment elsewhere, a network that provides information about job availability and perhaps the means to finance migration to a foreign job, and demand-pull confidence that, once abroad, a job will be waiting.

The demand-pull, supply-push, and network framework permits us to make two important points about economically-motivated migration:

Table 1
Determinants of Migration
Factors Influencing the Decision to Migrate

Type of Migrant	Demand-Pull	Supply-Push	Network/Other
Economic Migrants	Labor recruitment, e.g., guest workers	Un- or under-employment; low wages; e.g., farmers whose crops fail	Job and wage information; sons following fathers; family unification
Non-Economic Migrants	Family unification; e.g., family members join established spouse in destination country	Flee war and persecution; e.g., displaced persons and refugees/asylum seekers	Communication; transportation; Assistance organizations; Desire for new experience/ adventure

Notes:
1. Individual migrants may shift from category to category.
2. Pull, push, and network factors rarely have equal weights in any particular migration.
3. The weight of each factor in a particular migration stream tends to change over time.

- First, the three factors that influence an individual's decision to migrate rarely have equal one-third weights in any particular migration flow.
- Second, the weight of each factor often changes over time.

A common pattern is for demand-pull foreign worker recruitment to set international migration for employment in motion. Migrants are willing to be recruited because of the expected earnings gap at home and abroad, which reflects both demand-pull and supply push factors; wages times the probability of being employed induce migration.[13] However, network factors to become more important as the migration stream matures: "each act of migration alters the social context within which subsequent migration decisions are made, typically in ways that make additional movement more likely"[14] (Massey et al. 1993, 451). This means that, when recruitment is stopped, migration may continue, as supply-push and network factors sustain migration. [15]

Virtually all research on Mexico-U.S. migration begins with the premise that most Mexico-U.S. migration is driven by economic factors, broadly construed (Massey et al., 1994). There is also some non-economic migration across the Mexico-U.S. border, motivated by the desire to unify families in the U.S., and U.S. policies that encourage family unification. In addition, factors such as political persecution may push some residents to seek safety abroad, and other factors, such as the desire of teenagers and students for a new experience abroad, may encourage emigration.

Demand Pull

Most labor migrations begin inside the destination country, the U.S. in this case, as employers there, with or without explicit government approval, recruit and employ migrant workers from the sending country. During the early years of such labor recruitment, demand-pull factors tend to dominate reasons for migration, so that it appears that governments can open and close the foreign worker tap at will. In other words, indicators such as the number of vacant jobs or the unemployment rate can explain virtually all of the year-to-year fluctuation in the number of legally-recruited foreign workers arriving in an area.[16]

However, demand-pull, supply-push, and network factors usually evolve in a manner that yields one of the "principles" of international migration for employment; there is nothing more permanent than temporary workers (Miller and Martin, 1982). There are many reasons why temporary migrants can become permanent residents, or unauthorized workers can begin to accompany legal workers, including:

- migrants may gain legal rights to stay, as when they have their legal status renewed often enough to "earn" legal immigrant status,

- migrants may obtain the information or contacts needed to enter and stay unlawfully,
- employers may come to depend on migrants, and offer them jobs regardless of the government's recruitment policies or the worker's legal status,
- problems with the official recruitment system may encourage some employers and workers to avoid using it, promoting a parallel illegal migration system.

Why Demand-Pull?

There are several types of theories that seek to explain why immigration countries permit or tolerate the entry of foreign workers, and how the presence of foreign workers sets in motion factors that tend to make migration for employment a more or less permanent feature of a recipient country labor markets.

Structural dependence theories use as explanatory variables the evolution of attitudes of workers toward jobs, and adaptations of employers to immigrant workers, to explain how particular industries or entire economies come to rely on immigrant workers. Piore, for example, developed a worker attitude theory to explain structural dependence, arguing that only first-generation newcomers would fill certain jobs at the bottom of the labor market, so that the continued existence of these jobs sets in motion a migration for employment dynamic.

Piore's theory is based on the notion that there is a hierarchy of jobs that changes slower than do worker aspirations, creating a vacuum at the bottom of the labor market that attracts immigrants. Piore defined "bad jobs" in terms of wages, benefits, and promotion opportunities. Wayne Cornelius, among others, has a complementary theory that stresses that some jobs experience cyclical or seasonal layoffs, and that aging native-born workers want job security, so that native workers shun cyclical jobs, creating a demand-pull for immigrants to fill such jobs.

Cornelius considers industries to be structurally dependent on foreign workers if the employment of foreign workers does not change as unemployment changes over the business cycle—as when the demand for foreign workers persists despite rising unemployment (Cornelius, Martin, and Hollifield, 1994, 34). Some immigration researchers take this structural dependence idea one step further, arguing that employers prefer to hire foreigners, regardless of the unemployment rate, because the foreigners work harder and have better attitudes. In addition, the networks that bring foreigners into the work place often recruit and train new workers at no cost to the employer (Waldinger, 1996).

Rent-seeking theories of structural dependence begin from the notion that employers and other organized groups try to use government to obtain benefits for

themselves (Freeman, 1994). Groups that would benefit from an influx of foreign workers, such as farmers, seek government permission to employ them. Once enough employers believe that immigrant workers will continue to be available, underlying asset prices may change, giving asset owners an incentive to maintain the immigration status quo. For example, U.S. farm land prices have been estimated to be 10 to 20 percent higher because immigrant workers are readily available, so that farm wages lowered by immigration may account for up to $20 billion of the $100 billion value of U.S. fruit and vegetable land in the mid-1990s (Martin, et al. 1995).

Marxist and class theories assert that the world economy is organized in a manner that keeps emigration countries poor, and that distinct groups of workers in competition with each other are necessary to maintain work force discipline. For example, Marxist theories emphasize that development based on labor-saving technologies can never produce enough jobs, guaranteeing unemployment in emigration countries, and that the value-added in countries that export primary products is low, so that the wage gap between rich and poor countries will persist. The rural population remains poor and ready to emigrate because of slow growth in agricultural productivity, and because farm innovations that increase productivity displace rural labor.

In immigration countries, class theories argue that immigrant workers are needed to break strikes and otherwise play a buffer role in the labor market to make both native and immigrant workers docile. *Dependency theories* maintain that industrial nations permit immigration to keep emigration countries poor by taking from them their best and brightest (the so-called brain and brawn drains).

Some of these theories can be used to explain both why demand-pull factors initiate international migration for employment, and why such migration continues. However, most of these theories are too general to permit researchers to draw clear lines that demarcate initiating factors from sustaining factors. And, even if they can draw lines between initiating and sustaining factors at a point in time, few can explain why sustaining factors change.

For example, Mexican farm workers were first recruited legally by U.S. farmers during war periods, when farmers could argue that war unexpectedly reduced the supply of young men most available to be seasonal farm workers. Labor-intensive U.S. agriculture expanded during periods of legal Mexican labor recruitment, and in a manner that required a supply of workers willing to accommodate themselves to weather and other factors that determined exactly when the workers have employment. The U.S. need for flexible seasonal workers persisted after legal recruitment ended, and Mexican workers had become dependent on U.S. earnings, so the migration continued.

Another example illustrates how U.S. government policies can reinforce employer and U.S. worker perceptions about who does and should do certain types

of work. Seasonal farm work emerged as a last resort job because of the legacy of slavery and sharecropping, but also because farm work was the most common occupation assigned to prisoners and others under government internment. During World War II, when Mexican *braceros* (strong-armed ones) were recruited to work on U.S. farms, the U.S. government also offered the Japanese residents of western states who were interned in camps the chance to do farm work, and many did. In 1944 and 1945, Italian and German prisoners of war worked as farm workers. Finally, federal, state, and county prisoners were lent out to local farmers during harvest season to pay off their fines, a practice that continued until the late 1960s.

Once farmers make investments in orchards and vineyards that assume that a flexible supply or workers would continue to be available, they rationally fight for continued access to such workers to protect the value of their assets, as Freeman points out. However, as Piore notes, it is very hard for an industry that has become dependent on flexible immigrant workers to revert to native workers—unless there is a massive change in technology, wages, or job structure.

Bracero Recruitment

There was some Mexico-U.S. migration during most of the 20th century, but most Mexican-born persons in the U.S. today arrived after 1980. Recruitment was considered necessary in the 1940s and 1950s to set Mexico-U.S. migration flows in motion. There has always been considerable U.S. opposition to permitting farm employers to recruit Mexican workers—in the three most significant cases, in 1917, 1942, and 1951, "wartime emergencies" were the justification for permitting U.S. employers to recruit Mexican farm workers.

Seasonal U.S. employment seemed to be a perfect match for many farmers in West Central Mexico, who plant crops in June, after the summer rains begin, work in the U.S. during the summer months, and return to harvest their crops in October, after the U.S. harvest season is over. Between 1848 and 1907, there were no U.S. inspection stations on the Canadian and Mexican borders, and data on the number of Mexican immigrants arriving before 1907 refer only to Mexicans who arrived by sea, which was never more than 700 in any year before 1900 (Elac, 1961, 4, 33). Between 1900 and 1914, the peak number of Mexican immigrants admitted was 23,238 in 1912, but immigration fell to about 12,000 in 1913.

The first U.S. government-approved recruitment of Mexican workers occurred in 1917, when the U.S. Department of Labor suspended the head tax and the literacy test on Mexican workers coming to the U.S. "for the purpose of accepting employment in agricultural pursuits." The 81,000 Mexican workers admitted legally between 1917 and 1921 were required to work for the employer with whom they had up to a one-year contract or face deportation. Mexican immigration rose sharply,

from 17,900 in 1917 to over 52,000 in 1920, although the U.S. recession of 1921 led to the repatriation of an estimated 150,000 Mexicans.

Legal Mexican immigration increased in the 1920s, peaking at 89,300 in 1924—Mexican immigration averaged over 50,000 per year between 1924-1929. During the 1920s, the Mexican-born population in California tripled to 368,000. Mexican-born workers soon dominated the seasonal work force: a 1928 estimate was that Mexicans were 70 to 80 percent of the 72,000 casual and seasonal workers in California (Fuller, 1940, 19871). Repatriations and depression practically stopped Mexico-U.S. migration in the 1930s. Taylor (1937, 9) reported that there were about 150,000 migrant farm workers in California in 1935, and 200,000 to 350,000 nationwide, but did not mention Mexican-born migrants as an important group.

In 1942, U.S. farmers once again appealed for Mexican workers to produce "food to win the war." During World War II, admissions peaked at 62,000 in 1944, less than 2 percent of nation's 4 million hired workers. Between 1942 and 1947, some 220,000 Mexican *braceros* were admitted with government approval.

The Bracero Program that was created to deal with wartime labor shortages expired in 1947. There followed several years of informal and illegal movement. U.S. farmers were permitted to import Mexican workers, or employ illegal workers already in the U.S., after the U.S. Department of Labor certified labor shortages, and if the U.S. farmers offered the Mexican workers the same contracts guarantees that were required under the government-to-government program. However, neither the U.S. nor Mexican governments played a role in recruitment or contract enforcement.

There were tensions between the U.S. and Mexican governments. In the 1948 "El Paso incident," the U.S. government permitted several thousand "illegal Mexicans" to enter the U.S. over Mexican government objections, and then "paroled" or legalized them so that they could go to work for U.S. farmers (Hawley, 1966, 158-9).

The presence of Mexican workers diminished somewhat in the late 1940s. For example, a careful survey of some of the 100,000 farm workers in California's San Joaquin Valley in 1948 found only 15 percent Mexican-origin workers, and only one-third of them—about 5 percent of the valley's farm workers—were born in Mexico (Metzler and Sayin, 1950, 17).[17]

On July 12, 1951, over the objections of a President's Commission on Migratory Labor, PL-78, the Mexican Farm Labor Program, became law. President Truman, in reluctantly signing PL-78 into law, sent a note to Mexican President Alemán suggesting that the Bracero Program be only six months long to keep up the pressure on Congress to approve an employer sanctions bill.

President Alemán agreed that the U.S. and Mexico should combine "our efforts, in putting a definite stop to the illegal movement of agricultural workers" (quoted in Kiser and Kiser, 1979, 157). In 1951, Mexico's interior ministry announced that

it was "adopting new measures to have our border authorities keep a strict vigilance over the departure of our compatriots and prevent the departure of those who are not properly documented," and cooperating with defense and other ministries to "prevent the illegal departure of our compatriots from Mexican Territory" (Kiser and Kiser, 1979, 159-160).

These control measures were not effective. Instead of a government-regulated seasonal farm worker program, Mexican workers continued to arrive outside official channels and find U.S. jobs. According to Scruggs, "in Mexico there was no shortage of laborers eager to leave for the United States... many simply headed for the border without contacts of any kind in the U.S." (1960, 324). In the spring of 1954, the U.S. launched "Operation Wetback" to reduce illegal entries, and simultaneously made it easier for Mexican workers and U.S. farmers to employ legal *braceros*. As a result, the ratio of apprehensions to *braceros* was reversed between the early 1950s and the mid-1950s. In 1951-52, there were 5 apprehensions per *bracero* admission; by 1956-57, there were 5 *bracero* admissions per apprehension.

A summary of how the Bracero Program was administered is in Volume 3. See pages 869 to 974.

Together, the various "Bracero Programs" admitted about 4.6 million Mexican farm workers—perhaps one to two million individuals—between 1942 and 1964, and institutionalized a way-of-life that combined farming in Mexico and working for wages in the U.S. However, increased competition for the limited number of *bracero* slots in Mexico—the number of admissions peaked at about 445,000 in 1955—and the fact that U.S. farmers preferred to pay transportation to their farms only from the border, encouraged some Mexicans to move their families to the border area to improve their chances of being selected for admission as *braceros*.

It is perhaps worth noting that apprehensions—5.3 million—exceeded *bracero* admissions—4.6 million—between 1942 and 1964. The Mexican percentage of those apprehended fell from 99 percent in the early 1950s to 33 percent in the early 1960s, and the percentage of illegal Mexicans located in U.S. agriculture fell from 35 to 40 percent in the mid-1950s to 15 to 20 percent in the early 1960s (U.S. House of Representatives, Committee on Agriculture. 1963. 47). Both apprehensions and admissions measure events and not unique individuals—the same person could be apprehended several times, and the same person could be legally admitted as a *bracero* several times.

Most U.S. farmers did not employ *braceros*. In the late 1950s, almost 95 percent of all *braceros* worked on 50,000 farms in 5 states, meaning that 98 percent of the farms in the U.S. did not employ *bracero* workers (Hawley, 1966, 157).

The Kennedy Administration, which took office in January 1961, was determined to revise the Bracero Program to better protect U.S. workers by

Figure 1. Mexican *Braceros*, Apprehensions, and Immigrants: 1942--64

preventing Mexican workers from depressing U.S. farm wages. In October 1961, when President Kennedy "reluctantly" signed a bill to extend the Bracero Program through December 31, 1963, he asserted that "the adverse effect of the Mexican farm labor program as it has operated in recent years on the wage and employment conditions of domestic workers is clear and cumulative in its impact" (Congressional Research Service, 1980, 52). Kennedy order the U.S. Department of Labor to "prescribe standards and to make the determinations essential for the protection of the wages and working conditions" of U.S. workers (quoted in Congressional Record, August 15, 1963, 15215).

Table 2
Mexican *Braceros*, Apprehensions, and Immigrants; 1942-64

Year	Mexican *Braceros*	Deportable Aliens Located	Mexican Immigrants
1942	4,203	11784	2,378
1943	52,098	11,175	4,172
1944	62,170	31,174	6,598
1945	49,454	69,164	6,702
1946	32,043	99,591	7,146
1947	19,632	193,657	7,558
1948	35,345	192,779	8,384
1949	107,000	288,253	8,803
1950	67,500	468,339	6,744
1951	192,000	509,040	6,153
1952	197,100	528,815	9,079
1953	201,380	885,587	17,183
1954	309,033	1,089,583	30,645
1955	398,650	254,096	43,702

Temporary Worker Programs; Background and Issues. 36-37

In March 1963, the House Committee on Agriculture held hearings on whether the Bracero Program should be extended beyond December 31, 1963. Unions, churches, and the American GI Forum, an Hispanic veterans group, testified against extending the program. Farmers testified in favor of a two year extension, i.e., until December 31, 1965. On May 29, 1963, the House voted 174-158 not to extend the Bracero Program for two more years.

Mexico favored a two-year extension of the Bracero Program, pointing out that *braceros* sent about $35 million annually in money orders through the Bank of

Mexico to their families in Mexico, and that total remittances topped $100 million per year (Taylor, 1963, 42). In a June 21, 1963 note, the Mexican government asserted that the Bracero Program was "a result of the migration phenomenon... the absence of an agreement... would give rise to... the illegal introduction of Mexican workers into the United States."

Craig credits this Mexican note with tipping the balance in Congress in favor of extending the Bracero Program one more year, until the end of 1964 (1971, 195-6). The Senate voted 62-25 to extend the Bracero Program for one more year on August 15, 1963, and the House concurred in October, 1963.

As the Bracero Program wound down, did illegal Mexico-U.S. migration increase? The Mexican ambassador in 1963 noted that, as the number of *braceros* went down in the early 1960s, the number of apprehensions was stable, leading him to conclude that "Mexican workers have understood and accepted the fact that if they cannot obtain work by contract, it is because they would not obtain it either by entering the U.S. illegally" (quoted in Congressional Record, August 15, 1963, 15203).

Network Recruitment in 1996

Most of the community studies summarized below note that *bracero*-era recruitment set in motion migration flows that took on a life of their own. By the mid-1990s, these migration flows had evolved to move Mexican migrants across the Mexican-U.S. border without the active recruitment of workers in Mexico by U.S. employers.

Many U.S. employers today attract recently-arrived Mexican workers without sending agents into Mexico to recruit workers, or asking the Mexican government to recruit workers for them. For example, most rural areas in the midwest have unemployment rates under four percent, so meatpacking plants advertise in local media, but most rely on supervisors or current workers to recruit additional workers for them.[18] The worker recruitment network, in turn, handles entry across the border, transportation to the work place, and informal help learning the job.

The Chicken Trail

The Los Angeles Times on November 10-12, 1996 profiled one Mexican worker network in a three-part report on Mexicans and Mexican-Americans who followed the "chicken trail" from southern Texas to Missouri. Hudson Foods, based in Noel, Missouri, (population 1,169), paid a south Texas recruiter, B. Chapman & Co., $175 for each worker who showed up in Missouri for the $6.70 per hour jobs in its chicken processing plant. The reporter told how workers made their way north on

the “chicken trail” to work for Hudson and live in a converted motel, along with 135 other migrant poultry workers, for $45 per week per person (Rural Migration News, January and July 1997).

In 1994, Hudson employed about 1,200 workers to process 1.3 million chickens each week in Noel. Annual turnover exceeds 100 percent, so that Hudson hires about 50 new workers each month. Hudson employees are represented by a union. About 45 percent of the labor force are Latinos. Hudson paid a $20,625 INS fine in 1992 because many of them were not authorized to work. Hudson offers current employees who bring new workers to the plant a $300 bonus.

Hudson, the country’s seventh largest-poultry producer, with headquarters in Rogers, Arkansas, has 14 facilities in 11 states, more than 10,000 employees and expects $1.4 billion in sales for 1996.

The reporter-worker described the wet, the 47-degree temperature inside the plant, the semi-automated “disassembly” line and the lack of training for newly hired workers. The number of broiler chickens processed in the U.S. each year has more than doubled, from 3 billion per year in the early 1970s to 7 billion per year in the mid-1990s.

Hudson’s human resources director was quoted as saying: “there’s a large number of jobs that very few citizens in the U.S. want to do, but they’re there and they need to be done.... One of the social goods the poultry industry provides is employing people who would otherwise have a great deal of trouble getting employed.”

The labor recruiting company travels to industry shows in search of employers seeking unskilled labor and then offers to recruit workers for theses companies. According to the reporter, the recruiting company checked workers’ identification cards and took urine samples to test for drugs on the particular trip reported. The Border Patrol checked the Greyhound passengers identification cards in Falfurrias, about 75 miles north of the Mexican border.

In 1994, the owner of the motel where newly-arrived poultry processing workers were housed bought what was then a run-down hunting lodge motel for $220,000 and reopened it to house migrant chicken workers. Because poultry work is considered nonfarm work, it is not subject to special farm worker housing inspection, only normal local health and safety screening. The motel management takes every new Hudson worker to apply for food stamps at the Division of Family Services and the number of Latinos receiving food stamps in Noel increased from 35 per month in 1993 to 375 per month in 1996. In 1997, Hudson invested $3 million to build 60, 920-square foot duplex units that it rents to newly arrived workers.

Hudson is the economic linchpin of Noel, Missouri, but Hudson pays no property taxes to the city. The number of Latino students in Noel’s elementary school rose from 25 to more than 100. Hudson and nearby Simmons Foods contributed $12,000 to Noel schools in 1996.

The Beef and Pork Trail

The U.S. meatpacking industry has experienced four major changes since World War II. First, there has been a change in dietary habits—the average per capita consumption of chicken increased to 70 pounds per person per year in 1995, while that of beef and pork fell to 67 and 52 pounds per person. Second, there have been technological changes that moved meat packing away from urban consumers of meat and into rural areas closer to farmer-producers of cattle and hogs. Boxed beef, vacuum packing, and lower wages in rural areas were among the reasons why it became preferable to prepare retail packages of meat close to where animals are slaughtered.

Third, changes in the labor force, especially after 1980, have led to more unskilled workers, women, and immigrants in the plants—women traditionally have played a more important role in poultry processing than meatpacking. The union master agreement disappeared as three new meat packers replaced a number of century old businesses, and real wages fell. The real hourly earnings of meatpacking workers peaked in 1979, when meatpacking workers earned almost $15 per hour in 1992 dollars, and almost 20 percent more than the average manufacturing worker; in 1994, by contrast, real earnings were less than $10 per hour.

Fourth, both the raising and slaughter of animals became concentrated in fewer and larger operations. In some cases, meatpacking plants were located next to huge feedlots that were owned by the major packers. The cost of the animal remains the largest single cost of meat packing—cows costs slaughterhouses $0.60 to $0.70 per pound, and hogs $0.40 to $0.50 per pound, and "disassembling" these animals into meat products costs $0.05 to $0.10 per pound for beef, and $0.20 to $0.25 per pound for pork.

In a modern plant, 1200 250-pound hogs can be processed per hour, or 16,000 to 18,000 per day on two eight-hour shifts. The hogs are stunned, hung by one leg, stuck with a knife, and then carried through washing and singeing machines to remove hair. Carcasses are then split, internal organs removed, and various cuts of meat removed as the carcass travels past workers armed with knives. About one production worker is required for each 10 hogs slaughtered on a daily basis. The job hierarchy in most plants is relatively flat, meaning that there are relatively few production jobs that pay twice the entry-level wage.

Turnover is very high, so meat packers are constantly recruiting workers. Meatpacking plants advertise for workers in local media, and some offer bounties of e.g., $200 for each new worker referred. Some have both local recruiters, and recruiters who travel to e.g., Texas or California, to seek workers. The striking difference between meatpacking and seasonal agriculture is that meatpacking offers year-round jobs and annual earnings that are high enough to support a family,

so that the issues associated with the arrival of families—housing, schooling, health care—become important community issues early in the migration process.

Adjusting to Fewer Mexican-born Workers

There is one example of a U.S. industry adjusting to the removal of Mexican-born workers—the U.S. processing tomato industry—that shows how the supply of immigrant labor can create and sustain a demand for such labor.[19] In 1960, a peak 45,000 workers (80 percent *braceros*) were employed to hand-pick 2.2 million tons from 130,000 acres of the processing tomatoes used to make ketchup. In 1996, about 5,500 will be employed to ride on machines and sort almost 12 million tons of tomatoes harvested from 360,000 acres, a record crop.

In 1960, the average American consumed 44 pounds of processed tomato products. In 1994, per capita consumption of processed tomato products was about 75 pounds, versus 13 pounds per capita of fresh tomatoes. The real price of processed tomatoes in California fell from $30 per ton in 1960-61 to $22 per ton in 1970-71 (Brandt and French, 1981, 92). Processed tomatoes account for three-fourths of the 105 pounds of processed vegetables that the average American consumes. The U.S. exports about 5 percent of its processing tomato products.

In the early 1960s, when there was discussion of ending the Bracero Program, California growers argued that "the use of *braceros* is absolutely essential to the survival of the tomato industry." Headlines in farm magazines read; "Without *braceros*, tomato growers will slash acreage" (California Farmer, July 6, 1963, 5), from 177,000 acres in 1962. Tomato industry leaders were unanimous that California would "never again reach the 100,000 to 175,000 acres planted when there was a guaranteed supplemental labor force in the form of the *bracero*" (California Farmer, July 6, 1963, 5), and the director of the California Department of Agriculture testified that, without *braceros*, "we could expect a 50 percent decrease in the production of tomatoes" (U.S. House of Representatives, 1963, 61).

In fact, the termination of the Bracero Program in 1964 accelerated the mechanization of the harvest in a manner that quadrupled annual production in California from 3 million tons in 1960 to 12 million tons in 1996. The mechanical harvesting system spread quickly—in 1962, only 1 percent of California processing tomatoes were harvested mechanically. By 1969, 100 percent of the tomatoes were harvested by machine—the pace at which the machine was adopted traces out an S-shape. Cheaper tomatoes permitted the price of ketchup and similar products to drop, helping to fuel the expansion of the fast food industry.

The development of the tomato harvester was unusual. Unlike the usual approach to mechanization, in which engineers try to adapt the machine to the plant, so that e.g., a tobacco harvester can repick a field several times, tomato

mechanization utilized a systems approach in which scientists redesigned the plant so that most of the tomatoes would be of the same size, and most would ripen at the same time, and engineers developed a mechanical harvester that cut the plant, shook off the tomatoes, and then relied on electronic eyes to quickly pick up and sort red and green tomatoes (Rasmussen, 1968). Most of the research was done at the University of California-Davis, at a cost of about $700,000; the major private manufacturer spent an additional $500,000 to produce machines (Seckler and Schmitz, 1969, 14).

As one result, the work force and the wage system changed. In this case, local women paid hourly wages to sort machine-picked tomatoes replaced *bracero* men who earned piece rate wages to hand-pick tomatoes. According to one account, "Before the tomato harvester, tomatoes were harvested largely by *braceros*... recruited from rural villages in Mexico... [attracted by] unusually good wages." Employers asked their year-round tractor drivers and irrigators to bring their wives to ride on the tomato harvesting machines, and many did—the tomato harvest labor force changed from over 95 percent male in the early 1960s, to over 80 percent female by the late 1960s (Friedland and Barton, 1975, 59-61).

The tomato case illustrates what happens when wages rise, and there is labor supply shock. Farm wages in relation to farm machinery prices reached their low points in 1949-51, and again in the late 1950s. Beginning in the late 1950s, when the U.S. Department of Labor stepped up its enforcement of Bracero Program wage regulations, the wages of farm workers rose in relation to machinery prices, peaking in the early 1970s.

This illustrates a general point about the continuing demand-pull "need" for immigrant workers; if they are not available, and wages rise, there is a strong incentive to find labor-saving substitutes. However, if workers are readily available at low wages, the supply of labor can create its own demand—if immigrant workers are available, some factories or industries will adjust to employ them.

After a decade or more of dependence on immigrant workers, these firms and industries will argue that it is impossible to operate without immigrants. And they are correct; after the tomato harvest was mechanized, tomato growers had to get big enough to justify buying a harvesting machine, or they switched to other crops—over half of the farms growing tomatoes in 1960 were not growing them in 1970.

The tomato experience suggests that dependence on immigrant workers is often a one-way street, in the sense that market forces alone will increase rather than decrease the employment of immigrants over time. However, government policy can affect labor supply and technological choices, as the tomato case demonstrates, meaning that the extent of U.S. demand-pull for Mexican immigrant workers can be changed by U.S. immigration, trade, and technology policies.

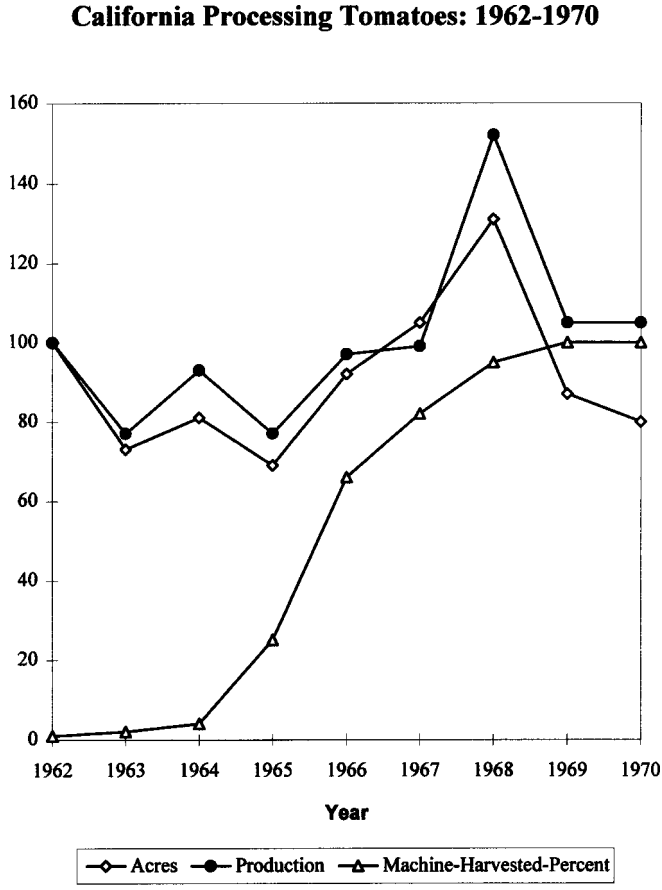

Figure 2. California Processing Tomatoes: 1962-1970

Changing government policies to reduce employer reliance on immigrant workers is not easy. In the U.S. in the 1960s, the U.S. Secretary of Labor devoted an enormous amount of time to a program that admitted fewer than 200,000 Mexican workers for less than 1,000 farmers, in a time when the U.S. labor force included 75 million workers. As long as there are U.S. occupations and industries that are dominated by immigrants, there will be ports of entry for immigrant workers. Government policies that change the supply of labor can lead at least some producers to adapt with labor-saving technologies, investment abroad, or re-organizing work.

In some cases, technological and market changes can expand the demand for immigrant workers if they are available. The U.S. meat-packing industry, for

example, was able to reduce wages and hire an immigrant work force during a technological shift that moved many jobs from retail stores to the packinghouses, and shifted the location of many plants. The electronics industry in California expanded during the 1970s and 1980s and hired immigrant workers to fill many of the new jobs created.

Mexicans in the U.S. Labor Market

In July 1996, there were 134 million U.S. residents employed (127 million) or actively looking for jobs (7.3 million), for an unemployment rate of 5.4 percent. Most workers in the United States are native-born U.S. citizens. In no U.S. state or city, and in none of the six major occupational or nine industrial sectors broken out in published labor force data, are immigrants a majority of the labor force.

Most U.S. economic data array individuals by race/ethnicity or U.S. versus foreign born rather than citizen–non-citizen categories. Thus, monthly labor market data collected from 60,000 households (the Current Population Survey) reports employment and unemployment data by sex, age (16 to 19 and 20 and older), and race (Black) as well as ethnicity (Hispanic), but not by citizenship and country of birth.

In October 1994, according to the Current Population Survey, there were 14 million foreign-born persons, and 118 million U.S.-born workers, in the U.S. labor

force, making foreign-born workers about 11 percent of the 132 million labor force.[20] Half of the foreign-born workers—6.4 million—were Hispanic, and two-thirds of these immigrant Hispanics—about 4.1 million—were born in Mexico. This means that Mexican-born workers are about 3 percent of the U.S. labor force.

Of the 4.1 million Mexican-born workers in the U.S. labor force in October 1994, 3.7 million were employed, and 380,000 were unemployed, for an unemployment rate of 9.3 percent at a time when the overall U.S. unemployment rate was 5.5 percent.

Mexican-born workers are a larger share of employment in some industries and occupations than others. For example, about 12 percent of those employed in agriculture and forestry in October 1994 were born in Mexico, as were 5 percent of those employed in construction and manufacturing. By occupation, about 7 percent of those with farming occupations were born in Mexico, and 5 percent of the operators and craft workers in the U.S. were Mexican born.

It is easy to exaggerate the role of Mexican-born workers in the U.S. labor market. Of the 400+ detailed occupations in U.S. labor statistics, there are only a handful of major occupations in which Mexican-born workers are perhaps a majority of all workers, including janitors and cleaners, household workers, and farm

Table 4
Employment by Selected Occupation: 1994–2005 (000)

	1994	If 50% Mex-born	2005	Total New Jobs	Growth	Replace-ment
Janitors and cleaners, including maids	3,043	1,522	3,602	1,140	559	581
Food preparation workers	1,190	595	1,378	282	188	94

Helpers, construction trades	513	257	581	429	68	361
Vehicle washers and cleaners	249	125	299	133	50	83
Total	7,809	3,905	8,426	2,726	617	2,109

New jobs include job growth and worker replacement.

Silvestri, George. 1995. Occupational Outlook to 2005. Monthly Labor Review, Vol 118, No 11, November. 64-78.

workers. Indeed, if half of the workers in the eight "immigrant" occupations below were Mexican born in 1994, then the following eight occupations would account for all Mexican-born workers employed in the U.S.

These occupations, which employed 7.8 million workers in 1994, are expected to employ 8.4 million in 2005, an increase of 600,000. But the number of new workers expected to be hired in these occupations is 2.1 million, or 3.5 times more, because these tend to be high turnover occupations that entry-level workers abandon as soon as they can find better jobs.

Replacement explains why the demand-pull of jobs may exist even in a declining occupation or industry. The highest worker replacement ratios are found in occupations such as food counter and related food service occupations, the typical case is a fast food restaurant with one manager over 25 and a crew of 10 to 20 workers under 25. Note that BLS projects that there will be about 37,000 vacancies per year for farm workers, or 25,000 per year for garment sewers, illustrating that, even in shrinking occupations, employers may be eager to employ recently arrived immigrants.

Labor Shortages and Welfare Reform

In 1997, the U.S. labor market is in a period of transition. First, unemployment is dropping even as the labor force is expanding. The U.S. labor force expanded by 1.3 million workers per year in the early 1990s, but expanded by 3.7 million in the 16 months of January 1996 through April 1997. Between January 1, 1994 and June 1, 1997, the U.S. economy has added about 8 million jobs.

The U.S. labor force of 140 million normally increases by about 1 percent or 1.4 million per year. The U.S. labor supply has been expanding about twice as fast, due to immigration, welfare recipients moving more quickly to work, more older men working, and an increase in the percentage of working-age women seeking jobs.

At the same time, the U.S. unemployment rate was 4.8 percent in May 1997, the lowest rate since November 1973. The result has been a flurry of reports of labor shortages, even for unskilled and entry level workers. In response, some of the largest U.S. employers of low wage workers—defined as hourly wages below $8.50, roughly the wage used by the federal government to determine eligibility for federal housing, child care and food subsidies—have formed the 26-member Employer Group to better find and keep stable, low-wage workers. About 80 percent of the 600,000 U.S. workers at McDonald's earn about $6 an hour, 80 percent of Marriott International's 185,000 workers earn $8 per hour, half of Hyatt's 40,000 employees earn less than $8.50 an hour. About 90 percent of Levi Strauss's 19,000 U.S. clothing production workers earn about $8 an hour. Collectively, the Employer

Group employs about 2.5 million U.S. workers, and says that "market realities" make it impossible to raise wages significantly.

According to the employer group, worker productivity reaches maximum sustainable levels after three years on the job. To retain workers, these employers are exploring ways to help their employees to find adequate child care, reliable transportation, and affordable housing. ConAgra estimates that it costs the company $2,000 to $3,000 to train a worker to understand health and safety standards and to learn how to properly trim meat off an animal carcass.

While U.S. employers are worrying about how to find and keep workers in entry level jobs, welfare administrators are trying to find jobs for recipients. Under the welfare reform, an additional 140,000 current welfare recipients are expected to be pushed into the labor force each year over the next five years. Most specialists divide adult welfare recipients into three categories: a group capable of getting jobs, but temporarily down on their luck because of illness or divorce; a second group that needs training and incentives to find jobs; and a third group that may not prove employable.

The number of welfare recipients has fallen sharply, as the most employable recipients find jobs. There were a peak 14.4 million U.S. welfare recipients in March 1994, 12.1 million in August 1996, and 10.7 million in May 1997, the lowest number since 1970. In California, the number of recipients peaked at 2.7 million in March 1995, and 2.4 million in May 1997. The Council of Economic Advisers estimated that 44 percent of the decline in welfare was due to economic growth, 31 percent to welfare reform and the rest to other factors.

In many cases, immigrant workers, fears of labor shortages, and high welfare caseloads go together. For example, in the San Joaquin Valley of California, about 75 percent of the 400,000 individuals who work as farm workers sometime during a typical year are immigrants, including 100,000 or more unauthorized migrants. Farmers fearful of labor shortages are calling for modifications of the H-2A program to make it easier to obtain temporary foreign farm workers. At the same time, 25 percent of the 761,000 residents of Fresno county are receiving some form of welfare assistance, and the unemployment rate in most months is over 10 percent.

Economic theory has little to say about why natives shun certain jobs, or how to respond to employer pleas of labor shortages, because economics rests on the assumption that changing prices or wages will eliminate any tendency of U.S. workers to avoid certain jobs, and cure any labor shortages. For example, neither of the 1994 review articles by Borjas and Greenwood mention labor shortages or native avoidance of "immigrant" jobs. In other words, the economic reasons for labor shortages and the solutions to them are one and the same—raise wages.

A review of the why-do-natives-avoid-certain jobs literature suggests two conclusions:

- reasons offered for job avoidance tend to be discipline-specific, e.g., economists discuss why rational individuals might find it economically rational to remain unemployed rather than accept immigrant jobs, geographers stress spatial disparities in the location of workers and jobs, sociologists point to rising expectations among nationals unwilling to accept low-status jobs, and lawyers look to rules and regulations that restrict immigrant access to particular jobs.
- the lack of a comprehensive theory of job avoidance means that there is little consensus on the relative importance of variables such as information, wages, working conditions, worker (im)mobility, or legal and social status in explaining why nationals avoid certain jobs, and little sense of the dynamics of change in such factors, as might occur if some jobs were first avoided because guestworkers were restricted to them and later became isolated as immigrant networks "took over."

How can the U.S. deal with the twin problems of getting work done and finding jobs for unskilled workers? The literature on filling "bad jobs" suggests that:

- preventing jobs from being shunned by nationals is far better than trying to re-attract nationals into such jobs after immigrant workers have gained a foothold.
- changing the supply of national workers for "bad jobs" becomes increasingly difficult over time, as immigrant networks isolate and effectuate changes in both labor supply and demand that make it very costly and difficult to re-attract nationals into "immigrant" jobs.
- most policies that succeed in dealing with bad jobs do so by reducing the number of or eliminating such jobs, not by re-attracting nationals into them.

Reducing or eliminating "immigrant" jobs can often be accomplished most efficiently with non-labor market measures, such as liberalizing trade to eliminate agricultural jobs, subsidizing labor-saving automation or self-service means of performing the work, taxing reliance on immigrant workers, or encouraging investment abroad.

Supply Push

Why Supply-Push?

Individuals migrate, and most theories of why people cross borders for economic reasons are based on the economic notion that individuals try to maximize their economic well-being, and they will migrate if they expect their economic status to

improve. The classic theory was developed by Todaro (1969), who emphasized that a rational person contemplating migration would compare the present value of the earnings she expected to receive where she now lives with expected earnings in another country, and move if expected earnings—wages times the probability of finding a job—were higher. Expected earnings would be higher, of course, if the migrant could legally cross borders and be assured of a job at higher wages, as under guest worker systems.

According to economic theory, emigration puts upward pressure on expected earnings in the origin, and downward pressure on expected earnings in the destination, and migration continues until an equilibrium is reached in which the expected earnings gap equals all costs of migrating, including psychic costs. Empirical studies find that expected earnings are a good guide to the direction of migration—individuals do tend to move from areas in which expected earnings are lower to areas of higher expected earnings.

Some analysts argue that the two major factors that determine expected earnings—wages and (un)employment—play different roles in migration decisions. Wage differences, the argument runs, make an individual prone to migrate, while job losses in the area of origin prompt emigration.

Many recent empirical studies begin with this expected earnings framework, and then expand it by considering, e.g., an individual's expected earnings' contribution to a multi-person household (Taylor, 1987), or how households use emigration to:

- overcome crises that result from e.g., a lack of insurance,
- obtain savings for investment when there are few local moneylenders or,
- obtain the funds needed to buy the consumer goods that neighbors were able to purchase with savings and remittances (Stark, 1991).

According to Taylor, et al., (1996, 404), the new economics of migration is based on the hypothesis migration "originate(s) in the desire to overcome market failures that constrain local production... [so that migration can be] an intermediate investment that facilitates the transition from familial to commercial production... [remittances can] loosen constraints on local production, once migrants become established abroad" (1996, 405).

In evaluating these theories of why individuals migrate for economic reasons, it seems prudent to remember that all begin from the expected earnings gap. In most cases, on a scale of 1 to 10, expected earnings differences are 80 to 90 percent of the reason why a person moves, with the extending explanations accounting for the rest. The fact that the research literature focuses on the extensions rather than the basic model should not obscure its importance.

Mexican Labor and Social Conditions: 1980–1994

Mexico has had a roller coaster economy since 1980, falling from an oil-inspired boom in the late 1970s into a debt crisis in 1982-83, then opening to the world economy in the mid-1980s, entering a pre-NAFTA boom in the early 1990s, and suffering a peso devaluation and economic depression in 1994-95. In 1997, the Mexican economy appears to be back on track, expanding at twice the U.S. economic growth rate.

During the roller coaster 1980s, standard social indicators improved, albeit at a slower pace than in the 1970s, as the government rationalized and improved the efficiency of its services. For example, the life expectancy of men rose from 63.7 to 66.4 between 1980 and 1990, and to 68.5 by 1995. Women life expectancy rose from 69.9 to 73.0 during the 1980s, and faster rate after 1990, reaching 75.5 by 1995. By 1995, life expectancy in Mexico exceeds that of some of the wealthier Latin American countries, including Argentina, Brazil and Colombia.

Similarly, illiteracy also fell during the 1980s, dropping from 17 to 12 percent of the population. The growth primary school enrollment between 1988 and 1994 was 2 percent per year, while the growth of children in this age group was only 1 percent per year, suggesting that more children are in school. By 1995-6, preschool attendance reached a historic high, including almost 80 percent of those of kindergarten age (Segundo Informe de Gobierno de Ernesto Zedillo). Mexico recently raised compulsory schooling from six to nine years; about 42 percent of 15 to 19 year olds are in school. About 20 million children are expected to be enrolled in K-12 Mexican schools in fall 1997, versus 52 million in the U.S.

In August 1997, President Ernesto Zedillo announced a $155-million PROGRESA program aimed at breaking the cycle of poverty in Mexico. Up to 177,416 families in parts of 10 states will get $8 a month to keep young children in school, with the payments higher for girls than boys, and rising with age. Unlike Solidarity, the Salinas Administration antipoverty program, PROGRESA is to be administered by the states.

During the eighties, the number of dwellings that lacked piped water supplies fell from 28 percent to 20 percent, and fell further to 19 percent by 1994. The share of housing units without sewage facilities fell from 36 percent in 1990 to 34 percent in 1992, while the share of households with electricity rose from 88 to 89 percent.

These improvements in social indicators can be attributed to improved service delivery during the 1980s, rising incomes after 1987, and the social program developed during the Salinas administration, *Programa Nacional de Solidaridad* (PRONASOL), which involved local residents in the provision of basic

infrastructure. This program has been criticized for serving electoral rather than strictly social welfare objectives (Dresser 1991, Molinar Horcasitas 1994, Roberts and Escobar 1997), since PRONASOL paid particular attention to municipios and states where the dominant party (PRI) had lost elections in 1988. Spending was also targeted to states with crucial upcoming elections, and there was no clear relationship between the level of poverty of different states and their per capita PRONASOL investment. Nevertheless, it must be said that PRONASOL delivered services in many poor states and regions, and that these improvements are evident in macro social figures and indicators.

From a supply-push perspective, worsening social indicators such as health or education or housing did not play a significant role in the rise of emigration seen during the 1980s. However, some of the states that became significant sources of emigrants in the 1980s did experience at least a stagnation in the improvement of social indicators, including the northern border states, where housing conditions deteriorated, partly because of rapid urban growth. In the South and Southeast, life expectancy stagnated and fertility and infant mortality remained very high in states such as Oaxaca and Guerrero.

Finally, a full appraisal of social conditions during the 1980s should acknowledge that, even though earnings continued to improve during the 1980s, the restructuring of employment meant new and often worse work conditions, including more frequent spells of unemployment.

Developments in the Mexican labor market since 1982 can be divided into three periods, one characterized mostly by adjustment, a second one by restructuring, and a third, the "crisis of 1994." Adjustment, restructuring, and crisis occurred under a longer-term era of growing mismatch between labor force growth that exceeded job growth, especially after 1975. In 1995, were 1.2 million persons turning 15. However, the number of new labor force entrants will begin to decline by 2000, and then slow significantly by 2010.

In 1982, the peso was devalued by 80 percent against the dollar, and there followed a period of adjustments marked by five factors that affected migration:

1. Earnings fell sharply, by an average 23 percent between mid-1982 and mid-1983, mostly as inflation outpaced earnings growth, and the incomes of those at the top of the earnings distribution fell even more, producing what some analysts called "equality through impoverishment" (Cortes and Rubalcava 1989). The ratio of U.S. to Mexican wages jumped from about 2.2 to 1 in 1981 to 6 to 1 by the end of 1983.

2. Unemployment did not rise significantly, except for an uptick in 1983, as adjustments occurred mostly through lower earnings (Lustig 1992).

3. Some women entered the labor market to offset falling male earnings. After 1982, married women with young children began entering the labor market, including poorer women in their 30s with young children who went to work for wages to maintain family income. In Guadalajara, for example, poor women going to work were able to make offset about two-thirds of the incomes that their husbands lost through lower real earnings after 1982 (Gonzalez de la Rocha).

4. However, there were few new formal sector jobs created for these women, except for an additional 400,000 jobs in *maquiladoras*, so that many of the women went to work as maids or in personal services.

5. Most Mexican firms adjusted to the peso devaluation by using more now-cheaper labor, which permitted them to be more flexible in meeting ever-changing consumer demand in what was still largely a closed market. However, in Monterrey, there was a comprehensive restructuring in some manufacturing industries, so that industries there emerged from the crisis more competitive. The overall manufacturing employment index, which was 100 in 1980, rose to 103 in January 1981, and then fell to 86 in January 1988.

In 1987-88, Mexico began to open its markets to the international economy. Mexico joined GATT in 1986, and again in 1988, Mexico lowered tariffs and removed import license requirements on many products. The October 1987 stock market crash led to capital flight from Mexico, and another peso devaluation, prompting the Mexican government, business leaders, and unions to sign the first pacto, or agreement on wage and price adjustments. Finally, in 1988 Carlos Salinas was elected President, ushering in a new era of privatization and opening markets to international trade.

The next six years in Mexico were marked by income growth but relatively few additional formal jobs. Between 1988 and 1994, real earnings began to rise, but formal employment in the manufacturing sector fell, agriculture began to be restructured, and the U.S.-Mexico wage gap narrowed from about 9 to 1 in 1988 to 5 to 1 in 1994, as the peso rose against the dollar, and as Mexican wages rose.

As Mexican wages rose after 1987, so did inequality, according to the National Survey of Urban Employment (Roberts and Escobar, 1996a). Income dynamics for the poorest 40 percent in Mexico are hard to track because the National Survey of Household Income and Expenditure reclassified many urban residents as rural (Escobar 1996). Independent analysts agreed with government findings that poverty increased from 1984 to 1989 (the number of those classified as very poor and in intermediate poverty rose), but also found that proportion of Mexicans with incomes below the poverty line rose between 1989 and 1992, when

government data showed that the percentage of residents in poverty was falling (Escobar 1996).

Beginning in 1988, many new labor force entrants found informal jobs in (personal) services or became self-employed; the manufacturing employment index fell from 86 in January 1988 to 73 in November 1994. The Mexican government permitted and encouraged labor market flexibility to increase productivity, and new labor agreements permitted many firms to restructure and reduce employment.

Agriculture underwent the beginnings of a withdrawal of government subsidies after 1988. Credits that did not have to be repaid were withdrawn, input subsidies and output price guarantees were reduced, and the land tenure system was changed. The combination of these agricultural policy changes and a rising peso discouraged exports, reducing the employment of hired farm workers, and also reduced the value of the crops that small farmers grew to sell. One result was that internal migratory circuits in Mexico that moved rural residents between small farms, jobs in export-oriented agriculture, and urban jobs were disrupted.

The one place where formal sector manufacturing jobs were created was on the border, in *maquiladoras*. But *maquiladora* jobs offered few opportunities for upward mobility, so that Mexicans had to decide whether to take "dead end" *maquiladora* jobs, or try their luck in interior Mexican cities, which offered fewer jobs, but more opportunity for upward mobility.

Employment grew faster than the labor force between 1992 and 1994. During that time, the informal share of total employment did not increase, real earnings rose, and unemployment fell—trends that were likely the result of more formal sector jobs leaving those with the fewest qualifications in the informal sector. This relatively good labor market performance in Mexico was not widely appreciated, in part because of skepticism about government data, and because of considerable economic restructuring that displaced workers, including in prosperous Monterrey. Between 1992 and 1994, the availability of jobs in Mexico seems to have reduced emigration—line-watch apprehensions per hour fell (Escobar, Bean and Weintraub 1996).

In December 1994, the Mexican peso was devalued, and it eventually fell over 50 percent against the U.S. dollar, from 3.45 pesos to $1 to 7.7 pesos per $1 in August 1997. Employment in Mexico fell sharply, as workers in both the formal and informal sectors lost jobs, even as real wages fell when inflation jumped. Bleak prospects for job seekers kept the labor force stable. For the first time in a decade, open unemployment rose faster than informal employment in 1995, especially for young people under 20, whose unemployment rate was above 20 percent for most of 1995.

The cheaper peso increased exports, but exporting firms added relatively few new workers, except in the border areas. Mexico's economy seems to be rebounding—it is expected to grow by about 8 percent in the second quarter of

1996, versus a 10 percent contraction in the same quarter of 1995. However, an August 5, 1996, Wall Street Journal article praising Mexican policymakers for sticking with economic reform—and thus, in the paper's opinion, laying the basis for higher savings and more productive investments—warned that, "in the next two years, at least, the outlook is for high unemployment and stagnant salaries... and a higher incidence of poverty" (Jonathan Friedland, "Latin America resists reform backlash," Wall Street Journal, August 5, 1996).

Mexican employers seem to be wary of hiring workers who might become fixed costs that limit their flexibility, so that labor market recovery may be delayed.

Mexican Agriculture

Agriculture represents a special concern for the Mexican government, and for northward migration. About 25 percent of Mexico's population lives in rural areas, the same as the rural share of the U.S. population, but most of Mexico's 23 million rural residents live on farms, while fewer than 10 percent of the 63 million rural residents of the United States live on farms.

In Mexico, the rural population generated only 8 percent of the country's $377 billion GDP in 1994, and rural incomes were less than one-third of Mexico's $4,180 per capita GDP.[21] From 1987 to 1992, per capita income among farmers declined by 32 percent, but there was not a significant rural-urban migration within Mexico. U.S. agriculture, by contrast, generates a slightly larger share of GDP than farmers' share of the population, so U.S. farmers have higher than average incomes, and much higher than average wealth.

Some 40 to 50 percent of all Mexicans are considered to be poor, and two-thirds of Mexico's poor people live in rural areas, as do three-fourths of the very poor (Levy and Van Wijnbergen, 1992, 498).[22] Although most of Mexico's population and rural poor are mestizos, the rate of poverty is highest among indigenous peoples in rural areas.[23]

Mexico's farming system is a creature of government and, for most of the 20th century, Mexican agricultural policies had the dual objectives supporting rural incomes by offering high government-guaranteed prices to farmers, and then providing consumers with basic foods at low prices. In practice, the subsidy system was more effective in reducing food prices for consumers than in raising farm incomes. The Mexican government was involved in all aspects of agriculture, from the distribution of land, to the provision of inputs such as fertilizer and credit, to the marketing and processing of commodities, and to the distribution of food to consumers.

Beginning in the mid-1980s, and especially in the early 1990s, the government began to withdraw from agriculture, accelerating what is likely to be a massive

movement off the land in Mexico. The government's withdrawal from agriculture in the 1990s was motivated primarily by the failure of the Mexican agricultural system to produce enough food at competitive world prices. In the early 1990s, Mexico's agricultural production stagnated, raising the bill for imported food. At the same time, rural poverty was widespread despite costly subsidies, and the government did not have the funds to re-capitalize agriculture. The Mexican government has announced several new initiatives, including a June 1997 policy: "A Defined Direction for Growth in the Countryside,'' which calls for the production of 37 million tons of basic grains by 2000.

Many Mexican farmers have network ties to the U.S. labor market. A 1994 household survey of the ejido sector collected information on 5,267 adults in the households interviewed (14 and older) and 9,216 adults in extended families. About 14 percent of the adults in the sample households, 19 percent of the adults in the biological family, and 38 percent of the household heads—whose average age was 49—had migrated to the U.S. at least once by the time of the survey (de Janvry and Sadoulet, 1997, 7).[24] Over 70 percent of those who migrated to the U.S. had less than 6 years of schooling. A detailed analysis of the 950 members of ejidatario families who have migrated to the United States found that more adult men under 35 migrate that men older than 35.

The Mexican government hopes that many farmers remain will remain in rural areas and switch from corn and beans to fruits and vegetables, especially as NAFTA accelerated the shift of North American fruit and vegetable production to Mexico. However, a careful analysis of trends in the North American horticultural industry suggests that most labor intensive agriculture will remain in the U.S. (Cook, et al., 1991). Mexico's primary competitive advantage in producing fruits and vegetables for the U.S. market is climate; Mexico can produce fresh vegetables during the winter months when most U.S. production areas except Florida are not producing. Even if Mexico were to completely displace winter vegetable production in Florida, most fruit and vegetable production would remain in the United States, because two-thirds of North American fruit and vegetable production occurs in the summer and fall, when Mexico is not producing significant quantities.[25]

Mexico is not likely to completely displace Florida as the source of most winter fruits and vegetables because, in many cases, low yields and low labor productivity make vegetable production more expensive in Mexico than in Florida. Most Mexican migrants, in any case, come from areas not likely to become export centers for fruits and vegetables.

Florida producers have also been adept at using the U.S. government to limit Mexican imports. The U.S. farm value of fresh vegetables and melons was $7.4 billion in 1995, and Florida's production of six winter fresh vegetables—tomatoes, bell peppers, cucumbers, snap beans, eggplant, and squash—represented about 10

percent of the total. Florida produced 2.5 billion pounds of these six fresh vegetables in 1995, other states produced 3.8 billion pounds, and 2.6 billion pounds were imported—about three-fourths of these fresh vegetable imports were from Mexico. Mexico exported about $1.5 billion of fruits and vegetables in 1995, including $600 million of tomatoes. The 16.5 pounds of fresh tomatoes that the average American eats each year, include about 4.6 pounds produced in Florida, seven pounds produced in other states, especially California, and 4.6 imported pounds, usually from Mexico.

Most of the year-to-year fluctuation in Florida and Mexico shares of the winter vegetable market has been due to weather, but in December 1994, the Mexican peso was devalued. Mexican fruit and vegetable exports surged in 1995-96, due to both the peso devaluation and to cold weather in Florida (Love and Lucier, 1996, 20).

Florida has filed two separate actions against Mexican winter vegetables, has lost one, and is likely to win the other—it should be noted that the 1996 "tomato war" does not hinge on tariffs—U.S. tariffs on Mexican tomatoes are low—$0.01 per pound—and are scheduled to be phased out in 2004. In the winter of 1996, prices for 25-pound boxes of tomatoes fell from the usual $10 to $12 to $3, below the $8 cost of production in Florida, and the $6 cost of production in Mexico. Florida and Mexico compete for less than half the year—for the five months between December and April—with the most severe competition in February-March.

Most observers attribute Florida's falling share of the winter vegetable market to weather and to Mexico's "correct" technological choices. Until the early 1990s, both Florida and Mexico produced mostly "mature green" tomatoes, which means that green tomatoes were picked into buckets, sorted and packed into cartons, and then gassed to turn them pink before being shipped to retail stores. However, Mexico began in the 1990s to plant "vine-ripe" tomato varieties that can be picked pink, and reportedly taste better than mature green tomatoes.

NAFTA permits governments to protect industries that are hurt by import surges, and Florida growers argued that a Mexican import surge in 1995-96 was hurting the U.S. tomato industry. But Florida growers lost this case in a 4-1 decision by the International Trade Commission on July 2, 1996, because most U.S. tomatoes are not produced in Florida—tomatoes are produced in California, South Carolina, and other states, and the "injury" clause of NAFTA does not consider one seasonal component of an entire industry. In response, Florida proposed, and the Clinton Administration supported, the redefinition of the Florida tomato industry as an "industry" for the purpose of invoking the NAFTA import-surge clause.

Florida producers filed a separate petition on April 1, 1996, that alleged that Mexico dumped tomatoes in the U.S. at less than their cost of production in 1995-96—they needed only show that there was "some injury" from imported tomatoes to win this case. The U.S. Department of Commerce investigated to determine,

e.g., whether Mexican tomatoes were sold at the same prices in Canada, Mexico, and the U.S. in 1995-96 but, just before it issued its decision, Mexico agreed to a price floor for its tomato exports—Mexican growers would charge at least $0.21 per pound, or $5.17 for a 25-pound box for their tomatoes shipped to the U.S.—and Florida growers agreed to suspend their dumping case. The Florida Department of Agriculture spent $1.5 million to press the tomato-growers' complaints against Mexican tomatoes.

Tomatoes and other winter vegetables are produced by a handful of large growers who rely on migrant Mexican workers in both Florida and Mexico. In Florida, four "family" farms dominate the Florida tomato industry—DeMare, Gargiulo, Heller, and Esformes—together they account for half of Florida's $400 million in annual tomato sales.

Mexico's export-oriented winter vegetable industry is centered in Sinaloa, about 600 miles south of the U.S. border. Large farms there employ about 170,000 Mexican workers for four to five months. Most of these seasonal workers are migrants; three-fourths migrate to Sinaloa from other parts of Mexico. In 1996, typical wages for tomato picking in Sinaloa were reported to be about $3 -$5 per day, and children often join their parents in the fields.[26]

The 1996 tomato war indicates that Mexican producers will not gain easy access to the U.S. market simply because NAFTA is in place. Even though most U.S. observers are not very sympathetic to the Florida growers—a recent story in the Wall Street Journal was headlined "With little evidence, Florida growers blame tomato woes on NAFTA"[27]—U.S. producers can wage effective campaigns to retard imports.

Given the difficulty of making the transition to labor-intensive fruits and vegetables, the key question is what will happen to farmers in Mexico. Most reports from rural Mexico in 1996 are dominated by discussion of a lack of credit and other obstacles that make it hard for farmers to switch crops and remain in agriculture.[28]

NAFTA and Supply-Push Migration

On January 1, 1994, the North American Free Trade Agreement (NAFTA) went into effect, laying the basis for an eventual free trade area encompassing 380 million people with a combined GDP of $7 trillion. The purpose of NAFTA is to reduce trade barriers and promote investment in the region, thereby stimulating economic and job growth throughout North America.

Migration played a background role during the Congressional debate over whether NAFTA should be ratified.[29] This was primarily because the migration message from researchers could be used by both opponents and proponents of NAFTA. The consensus among experts was NAFTA would contribute to an initial

increase in Mexico-to-U.S. migration, and decrease the cross border flow beginning in a decade or so (Martin, 1993). NAFTA proponents, who took a long-run perspective, argued that the prospect of eventually reduced migration was an argument in favor of NAFTA, while some NAFTA opponents opposed the agreement because of the predicted short-run migration hump.

Many observers expected Mexico-to-U.S. migration to begin to decrease as soon as the North American Free Trade Agreement (NAFTA) was signed. Former Mexican President Carlos Salinas de Gortari explained the relationship between NAFTA and migration in this way; "Today, Mexicans have to migrate to where jobs are being created, the northern part of our country. With NAFTA, employment opportunities will move toward where the people live, reducing drastically migration, within the country and outside of the country" (quoted in the San Diego Tribune, November 14, 1993, 1).

Trade-stimulated economic growth should also reduce emigration from Mexico; the U.S. Commission for the Study of International Migration and Cooperative Economic Development looked for "mutually beneficial, reciprocal trade and investment programs" to reduce unauthorized migration from Mexico and concluded that "*expanded trade* between the sending countries and the United States *is the single most important remedy*" for unauthorized immigration (1990, p. xv, emphasis added).

However, the commission warned that "the economic development process itself tends in the short to medium term to stimulate migration." Policies that accelerate economic growth, including privatization, land reform, and freer trade, can produce a migration hump, or temporarily more migration, creating "a very real short-term versus long-term dilemma" for a country such as the United States that wants to use free trade agreements as one means to curb unauthorized immigration (U.S. Commission, 1990, p. xvi).

Table 5
Canada, Mexico, and the United States (1995)

	GDP ($ bil)	GNP Per Capita $	Ratio-U.S.=100	Avg. Ann. Growth (1985-95)	Pop. (mil)	Avg. Ann. Growth (1990-95)
Canada	569	19,380	0.72	0.4	30	1.3
Mexico	250	3,320	0.12	0.1	92	1.9
U.S.	6,952	26,980	1.00	1.3	263	1.0
Total	7,771				385	

Source: World Bank Development Report, 1997.

NAFTA brought together 3 different countries in the world's largest free trade area. Canada and the United States have similar GNPs per capita, but their per capita GNP and population growth rates diverged since 1985—Canada has experienced slow economic growth and fast population growth compared to the United States. Mexico, in comparison to the United States, had a very slow real per capita GNP growth rate over the past decade, and its population grew at twice the U.S. rate.

The major economic effect of NAFTA should be to stimulate the flow of investment, goods and services across North American borders. There were more than 50 models that projected the effects of NAFTA on the economies and labor markets of Canada, Mexico and the United States, and most concluded that the economic effects of NAFTA in the United States were projected to be small, both because the Mexican economy is only 1/20 the size of the U.S. economy and because tariffs are already low—the average U.S. tariff on Mexican imports in 1991 was 4 percent, and the average Mexican tariff on U.S. imports was 10 percent.

Most of the models that considered NAFTA's effects on migration expected the agreement to increase the flow of Mexicans to the United States. The "smoking gun" in this migration hump scenario anticipates that the free trade in agricultural products envisioned by NAFTA will displace Mexican farmers who have a tradition of migrating to the United States.

The most widely-cited projection of NAFTA's effects on Mexico-to-U.S. migration was that of Hinojosa and Robinson (1991). Using a CGE model of the U.S. and Mexican economies and labor markets, and then projecting how freer trade might affect Mexican agriculture, they estimated that NAFTA would displace about 1.4 million rural Mexicans, largely due to changes in Mexican farm policies and freer trade in agricultural products.

If jobs are not created for these displaced farmers in the areas where they live—and few observers expect a significant number of "real" jobs to be created in these rural areas, Hinojosa-Robinson projected that 800,000 would stay in Mexico, and that 600,000 would migrate (illegally) to the United States. These 600,000 additional U.S.-bound migrants—say 100,000 per year over 6 years—are presumably NAFTA-caused additions to the "normal" flow of legal and illegal Mexican worker arrivals.

The reason why NAFTA increases migration in the Hinojosa-Robinson model is because of free trade in corn. Between 30 and 50 percent of all days worked in rural Mexico are devoted to production of corn and beans. U.S. farmers can produce both crops cheaper than Mexican farmers—the U.S. corn price of $95 per ton early in 1994 was less than half of the Mexican price of $205 per ton. Liberalizing trade in corn, as NAFTA does over 15 years—is expected to shift North America's corn production northward, at U.S. prices, since Iowa alone produces twice as much corn as Mexico.

Instead of slowing down change in agriculture, as these migration models would advise, the Mexican government speeded up agricultural changes. Mexico changed its farm policies in four important ways in the early 1990s:

- First, Mexico accelerated the withdrawal of input subsidies from agriculture, increasing costs for many farmers.
- Second, Mexico in 1991-92 freed up the land market, permitting ejido land to be rented or sold, and permitting foreign and domestic corporations to own Mexican farm land, in an attempt to attract capital into agriculture.
- Third, Mexico since 1987 has opened itself to freer trade in farm commodities, and NAFTA in 1994 locks in a schedule to achieve relatively free North American trade in farm commodities by 2009.
- Fourth, Mexico in 1993 switched its system of farm support from price guarantees to income transfers, eliminating the need for farmers to grow crops over the next 10 years to receive government support.

These policy changes amount to a revolution in Mexican government policies toward the one-third of the population in rural areas. Their net effect will undoubtedly be to promote emigration from rural Mexico.

Although no one knows how many people will leave rural Mexico during its expected "Great Migration," many echo Luis Tellez, the former Undersecretary for Planning in Mexico's Ministry of Agriculture and Hydraulic Resources, who suggested on several occasions that Mexico's rural population might shrink by 1 million annually, that up to 15 million rural Mexicans may migrate "within a decade or two" (Golden, 1991, p. A1).[30] After Mexicans leave the farm, Mexico's labor allocation should improve—Tellez frequently reminded audiences that 27 percent of the Mexican population depends on agriculture for a living, but this sector generated only 9 percent of GDP in the early 1990s, and for this reason includes 2/3 of Mexico's poor people.

The unanswered question is how many Mexicans displaced from agriculture will migrate to Mexican cities and find jobs, and how many will migrate to the U.S. Many new jobs in Mexico are being created in "mid-sized" Mexican cities both along Mexico's northern border, and in interior cities (Corona 1993, Browning and Corona 1995), but still not as many as were created in Mexico City, Guadalajara, and Monterrey in the 1970s, when fewer Mexicans were joining the labor force every year.

Changing Mexico

Mexico is rapidly urbanizing, and more Mexican migrants in the U.S. were born or have lived and worked in Mexican cities.

According to Wayne Cornelius, the urban origins and experience of more Mexican migrants matches neatly the demands of U.S. nonfarm employers for unskilled nonfarm workers. Interviews with Mexican-born workers in San Diego found that over half intended to stay permanently or as long as possible in the U.S. upon arrival, and only 20 percent were in the U.S. to save a target amount of money before returning to Mexico (Cornelius, 1997, 5). But intentions to stay in the U.S. increase with experience; two thirds of those interviewed said that, based on current circumstances, they would like to remain in the U.S.

Remittances and Development

Mexico receives $4 billion to $5 billion per year in remittances: the Mexican central bank reported in June 1997 that Mexicans in the U.S. remitted $4.2 billion in 1996, up from $3.7 billion in 1995. Mexicans reportedly had $10.3 billion in savings in U.S. banks in 1996.

Many researchers do not believe that emigration and remittances are a shortcut to faster economic development.

The new economics of migration stresses the multiplier role that their expenditure can have on local economic activity, the importance of foreign labor markets in overcoming the inability to borrow money locally, and the ability of foreign jobs to cushion the effects of recessions in the country of origin.

However the open question is what kind of government environment is needed so that remittances have their maximum development impact. Taylor et al. (1996, 411) assert that "Schemes to harness international migrant remittances for local development are destined to fail if governments do not create an economic environment that is conducive to investment in productive activities at home." This means that, under some circumstances, it may be better to "correct failures in local capital and risk markets" rather than e.g., create jobs (1996, 405).

Most of the money is sent to Mexico in small sums, often less than $300, and at a relatively high cost to sender and recipient. The cost of transferring these remittances is often 20 percent of the amount transferred. For a typical $300 transfer, Western Union in the U.S. charges $29 or 10 percent, and Elektra in Mexico turns remittances from dollars into pesos at an exchange rate that is about 10 percent less than the interbank rate.[31] This means that as much as $1 billion of the $4 to $5 billion destined for often poor areas of Mexico is absorbed by transfer costs.

In May 1997, the U.S. Postal Service and its Mexican partner, Bancomer, extended their wire cash transfer service, Dinero Seguro or Safe Money, from Texas to 200 post offices in Southern California. Dinero Seguro charges $15 for a wire transfer of up to $250, or a maximum commission of six percent. However, the

competitors to the Western Union-Elektra consortium often require several days to clear fund transfers, so that many migrants continue to use the higher cost service.

Networks

The demand-pull and supply-push factors that motivate and sustain migration have been likened to battery poles—they have the potential to start a car or a migration flow, but they act only when a link is established between them. Network factors are the diverse forces that demographer Everett Lee called "intervening variables," networks of friends and relatives, employers, labor smugglers and moneylenders who can tell potential migrants about conditions abroad, and provide them with the means to take advantage of opportunities abroad. According to one review, if demand-pull and supply-push factors explain why Mexicans migrate to the U.S., networks determine who migrates, and where Mexican migrants go in the U.S. (Wilson, 1993, 119).

Networks provide part of the explanation for why more Mexican migrants go to Los Angeles than Minneapolis. Neighboring Mexican villages illustrate the effect of networks: the village that sends many of its young men Los Angeles may have sent farm workers to the United States in the 1950s, so that today young workers from the village are informed in advance about where to go in Los Angeles to find jobs.

The village that sends few migrants, on the other hand, may not have many anchor friends and relatives in the United States to provide potential migrants with job and housing information. The fact that young people from this equally poor but less well networked village may well wind up unemployed in the United States helps to explain why fewer people from that village emigrate.

Most empirical studies find that network factors eventually increase in importance over time. In a process that has been termed "cumulative causation," each time a migrant leaves he "alters the social context within which subsequent migration decisions are made, typically in ways that make additional movement more likely" (Massey et al., 1993, p. 451). The explanation for snowballing migration is that migration "tends to increase in prevalence and become more diverse because transnational movement causes relatively permanent changes in individual motivations, social structures, and cultural milieus, and these changes cumulate over time to change the context within which subsequent migration decisions are made. As more people are induced to migrate, knowledge and network connections expand further, inducing more people to migrate, and so on" (Massey, Goldring, and Durand, 1994, 1528). Within the emigration area, there may be secondary effects, including changes in the distribution of income, changes in the distribution and usage of farm land, and changes in consumption habits.

Network Hiring

Most jobs at the bottom of the U.S. labor market are found by word-of-mouth and, after one or more immigrants is hired, an immigrant network is often established to provide additional workers as vacancies appear. The employer of low-wage and unskilled workers—a restaurant or hotel, a shoe or furniture manufacturer, or a farmer—typically experiences a high turnover of American workers because the Americans are dissatisfied with the low wages, hard work, and few benefits of these jobs.

The immigrants, by contrast, tend to report diligently every day, offer to bring their friends and relatives to fill vacant jobs, and even to train newly-hired workers. The loyalty and dependability of immigrants soon makes them, in the eyes of some employers, preferred workers. Using immigrant networks to find new workers offers employers several advantages; current workers know exactly what the job requires; current workers have an incentive to recruit only good workers; current workers transfer existing friendships, etc. into the workplace; and networks are a cheap and efficient way to obtain new workers.

Between 1942 and 1964, U.S. employers recruited workers in Mexico with the blessing of the U.S. and Mexican governments. Neither government endorses private recruitment for work in the U.S. today. However, indirect recruitment through migrant networks is widespread—U.S. employers often ask current workers to recruit family and friends to fill vacant jobs. In addition, many U.S. employers outside traditional immigration areas use U.S. and Mexican labor brokers to recruit immigrants, and they advertise on both sides of the border.

Case studies of immigration networks demonstrate how quickly certain jobs become the "property" of non-nationals. In Los Angeles, unionized Black janitors who cleaned high-rise buildings were displaced by non-union Mexican immigrants over a five year period in the early 1980s. This displacement occurred quickly and indirectly; according to a GAO report, the number of unionized Black janitors in Los Angeles county fell from 2,500 in 1977 to 600 in 1985, even though janitorial employment rose 50 percent in the county as a result of a building boom (GAO, 1988, pp. 40-1).

One reason for the displacement of unionized Black janitors in an expanding service industry is that the structure of the cleaning industry changed. Instead of hiring janitors directly, janitorial service firms that specialized in cleaning buildings developed, and they tended to employ recently-arrived immigrants to clean buildings for 25 to 35 percent less, in part because they paid lower wages, and in part because they offered fewer benefits. In the case of Los Angeles janitors, cleaning firms paid their immigrant workers up to two-thirds less than prevailing union wages. A subsequent study reported that inflation-adjusted janitorial wages fell 36

percent to $4.50 per hour between 1983 and 1988, and that the share of each rental dollar going to janitorial services fell from six percent to three percent (other estimates put the cost of cleaning at 10 to 12 percent of the cost of operating a building, when including costs from electricity and taxes to security).

The most recent study of network hiring was directed by Waldinger (1994). It described how employers in Los Angeles asked current immigrant workers to bring friends and relatives to fill job vacancies. These immigrants can draw from a seemingly endless pool of friends and relatives in the U.S. and abroad, and Waldinger found that network hiring tended to exclude e.g., native-born Blacks and whites, in part, because they did not learn about job vacancies, and in part because their reservation wages—the minimum wage they demanded to accept a job—were often 50 percent more than prevailing wages.

Why don't employers who are hiring large numbers of new workers encourage the establishment of a network of Black or white workers? Many employers believe that immigrants work harder, complain less, and in general have the "right attitude" toward their jobs and managers; they also "get along" with co-workers, in many cases friends and relatives who found them jobs. Interestingly, the "right attitude" was considered more important for many jobs than education or English.[32]

Surveys of employers who hire new workers through immigrant networks support the hypothesis that immigrants often get into certain jobs by accident or design, and then a process of cumulative causation is set in motion that ensures that nationals will not be recruited or attracted to "immigrant" jobs. It is in this way that direct immigrant-native worker competition for jobs gives way to indirect competition, as occurs when immigrant networks become "exclusive suppliers" of new workers for vacant jobs.

The U.S. in 1996 is taking two policy steps that may affect the demand for immigrant workers and the willingness of U.S. workers to accept "immigrant jobs." First, the U.S. minimum wage is scheduled to rise from $4.25 hourly to $4.75 on October 1, 1996, and to $5.15 on September 1, 1997, increasing the earnings of a full-time minimum wage worker employed 2,000 hours per year from $8,500 to $10,300 by 1998.[33] In 1995, about 3.7 million U.S. workers 16 or older were paid $4.25 or less per hour; they represented about 5.3 percent of all hourly-paid workers. Teens aged 16 to 19 are about one-third of those paid $4.25 or less; about 73 percent of all minimum wage workers are white.

The second U.S. policy change that may affect the "immigrant labor market" is welfare reform, which, inter alia, denies food stamps and Supplemental Security Income to most legal immigrants, and permits states to eliminate cash assistance and Medicaid for non-U.S. citizens. All states must file plans with the federal government to implement welfare reform by July 1, 1997, and review the citizenship status of persons receiving benefits within 12 months. There are believed to be

about 1.5 million legal immigrants in 1996 getting federal welfare benefits, and some may be pushed into the labor market.

There are about 4.6 million adults receiving welfare assistance, including 650,000 who are working or in training. States are required to have 25 percent of the adults receiving assistance working at least 20 hours weekly by 1997, and 50 percent working at least 30 hours weekly by 2002. The average adult receiving assistance has eighth grade skills, so that the planned welfare-to-work transition could add over 2 million largely unskilled workers to the U.S. labor market.

Communications, Transportation, and Rights

The U.S. is taking steps to make work pay more, and pushing more U.S. citizens and legal immigrants into the labor force. It is not clear these minimum wage and welfare policy changes will affect Mexico-U.S. migration networks.

Networks or linkages across the U.S.-Mexican border have been shaped and strengthened by three of the major revolutions of the past two generations; the communications revolution, the transportation revolution, and the rights revolution. The *communications revolution* refers to the fact that potential migrants know far more about opportunities abroad than did turn of the century migrants from southern and eastern Europe who set out for North and South America and Australia.

The major source of information about life abroad is countrymen already settled abroad who can tell the migrants about opportunities in the United States. Cultural gaps are also diminishing, making it easier for especially young people to consider working and living abroad.

The *transportation revolution* is simply the fact that the cost of traveling—relative to the wages that can be earned—has dropped enormously, while access to and the convenience of international travel has increased. The cost of traveling legally to the U.S. from most parts of Mexico is less than $500, and even illegal entry typically costs less than $1000. British immigrants who indentured themselves to migrate to the North American colonies in the 17th century, by contrast, often promised to work three to five years to repay one-way transportation costs.

The third network revolution that can turn potential migration into actual migration is the *rights revolution*, or the spread of individual rights and entitlements to all residents of the United States and other industrial democracies (Hollifield, 1994). Over the past 50 years, the industrial democracies have expanded their safety nets, and strengthened personal rights vis-a-vis government agencies, so that more residents, including foreigners, have human and work place rights, and are sometimes eligible for social welfare benefits. The rights revolution can strengthen networks by enabling even unauthorized foreigners who are present to increase the probability that they can remain in the United States.

Rights are created by governments, and frustration with their inability to affect communications and transportation has prompted many governments to roll back immigrant rights, especially for non-U.S. citizens. In the U.S., for example, unauthorized foreigners have seen their rights to social and other services curtailed over time, and new systems established to screen them out of social services and the labor market. Proposition 187, approved by a 59-41 percentage vote in California in November 1994, represented perhaps the most-discussed effort to discourage immigration by establishing a state-run system to keep unauthorized immigrants out of schools and social service programs.

Network factors may be very important in sustaining migration, but they are very hard to measure. The definition suggests why. Massey and Espinosa quote a definition of the social capital that undergirds networks; "the sum of the resources, actual or virtual, that accrue to an individual or a group by virtue of possessing a durable network... of mutual acquaintance and recognition" (Massey and Espinosa, 1995, 13). Such a definition can be operationalized to include a variety of hard-to-measure variables.

Past Case and Community Studies

This section has two parts; a "meta analysis" of community and network case studies completed before 1995, and a re-analysis of the Mexico Migration Project (MMP) data. Both parts illustrate how a migration process that began largely as demand-pull recruitment has evolved into a more complex migration relationship in which supply-push and network factors play ever larger roles.

Studies of Mexican communities that send migrants to the U.S. emphasize that most of the first migrants were men recruited to work on U.S. farms. However, very little active recruitment was necessary, especially in some villages, since the community studies emphasize that, even during the Bracero Program there was illegal migration to the U.S. alongside legal *bracero* migration. Mines (1982, 446), for example, notes that some migrants told him that "as undocumented migrants [during the 1950s] they earned higher wages and stayed for longer periods" then as legal *braceros*.

Past Studies

This section reviews community studies completed primarily by U.S. researchers to determine what factors were considered to be most important in (1) initiating and (2) sustaining Mexico-U.S. migration. We review them to highlight how the major factors initiating and sustaining migration have changed. The studies are summarized in the attached chart from oldest (top) to newest (bottom), and the

major factor motivating migration runs from demand-pull (left) to supply-push and network (right).

Case or community studies try to understand migration processes in a setting where the researcher can understand—the individual, household, and community context in which decisions to migrate are made. In most cases, researchers visit the community that they are studying for extended periods of time, interview 5 to 10 percent of the households, and then collect Mexican and sometimes U.S. community variables to explain the factors that initiated and sustained migration to the U.S.

First Wave Studies

The first studies of emigration communities were done by Taylor in Michoacán (1929, 1931, 1932, 1933). Taylor concluded that wage gaps motivated Mexico-U.S. migration and, once in the U.S., wage gaps between the border areas and northern states encouraged Mexican migrants to continue to Chicago and other Midwestern cities in search of employment.

One of the three *bracero* recruiting centers in Mexico was in the border state of Chihuahua, and Hancock concluded that Mexicans were eager to migrate to the U.S. because of higher U.S. wages. Hancock reported that average daily farm wages in the U.S. ranged from $5.90 in California to $4.67 in Arkansas, and from $0.89 in the Northern Pacific states of Mexico to $0.42 in the southwestern Mexican states, for wage ratios of between 7 to 14 to one (1959, 29). Although higher wages were the impetus for migration, Hancock noted that a *bracero* soon learned that "working people [in U.S.] have greater economic opportunities,... justice is more impartially administered, and that government officials treat ordinary citizens with more respect than usually is the case in Mexico" (1959, 38).

Hancock examined four of Chihuahua's 66 *municipios*—Aldama (population of 13,600 in 1957), Meoqui (20,800 in 1957), Guerrero (31,800 in 1957), and Janos (5,300 in 1957)—to determine the effects of emigration on them,

There were about 500 *braceros*—11 percent of the local labor force—from Aldama each year in the mid-1950s, and most reported that they had more work at higher wages in the U.S. than in Mexico (1959, 96). Meoqui had a *bracero* quota of 600 in 1957 and, once the effect of *bracero* emigration was to attract to Meoqui migrants from Durango, Coahuila, and Zacatecas to pick cotton.

Janos had no *bracero* quota and, while local officials asserted that no one wanted to emigrate, Hancock found several residents who had migrated illegally to the U.S., and observed that former *braceros* had a "friendly attitude" toward Americans (Hancock, 1959, 118). Hancock concluded that Mexicans wanted to work in the U.S. because of a range of factors—low wages, high living costs and

escaping the monotony of village life, but that "the causes of emigration... can be reduced to one salient fact: the Chihuahua economy is unable to provide employment adequate to support the state's population" (1959, 124).

By the 1960s and 1970s, community studies were noting that more factors played a role in motivating and sustaining migration. Wiest (1973) describes the effects of emigration on households in Acuitzio del Canje, a town of 3,600 in located near Morelia, Michoacán, and emphasizes that the U.S.-bound immigrants in the late 1960s were legal greencarders taking advantage of 15 to 1 income differences. Most of these "green card commuters" were former *braceros* who intended to return to the village.

Wiest reported that 24 percent of the migrants in 1966-67 who were out of the village were in the U.S., and that most had the right to live and work in the U.S.[34] In 1966-67, Mexicans employed on U.S. farms could earn $15 to $25 per day, versus $0.80 to $1.20 in local the day labor market—according to Wiest, "a relatively unskilled temporary job in Mexico provides a higher income than jobs... in Mexico" (1973, 203). Despite U.S.-Mexican wage differences, however, Wiest emphasized that most of the Mexican sojourners in the U.S. intended to return to Mexico; "regardless of the type of labor in the United States, the tendency is toward temporary residence there" (1973, 186).

Many former *braceros* became greencard commuters, traveling seasonally from homes in Mexico to jobs in the U.S. Cornelius (1976a, 1976b) described the process through which young men from several communities in Jalisco migrated to the U.S. for farm jobs without their families, both legally and illegally.

Reichert (1979, 1981, 1981) conducted interviews with 26 informants a decade later in Michoacán and, like earlier studies, and emphasized that most Mexican migrants in the U.S. were sojourners employed in agriculture. Reichert noted that, in the late 1970s, there was about 1 illegal migrant in the U.S. for every 2 legal migrants, and that the wage gap between seasonal farm jobs in the U.S. and Mexico had narrowed, to about $30 per day in the U.S., and $3.80 per day in Mexico. However, Reichert concluded that the expenditure of remittances was not promoting stay-at-home development; "money earned in the U.S. has enabled migrants to raise their standard of living to a level that can only be maintained through recurrent migration" (1981, 63).

Reichert and Massey (1979, 1980) used these data to separate migration from these villages into two phases; pre-1965 *bracero* outmigration, and post-1965 outmigration that increasingly involved women and children joining ex-*braceros* who had become legal U.S. immigrants. The U.S. policy of permitting U.S. employers to write letters offering ex-*braceros* jobs enabled many to become legal immigrants with the right to unify their families in the U.S.—one estimate in 1962 was that as many as 80 percent of the 55,000 Mexican immigrants admitted

to the U.S. were ex-*braceros* who obtained permanent labor certification (U.S. Senate, 1965, 22).

Roberts (1982) analyzed data collected from farmers in 1974 in San Luis Potosí, Guanajuato, Puebla, and Oaxaca, and found that, in all four Mexican states, a significant number of farmers in the early 1970s were also employed off the farm, and some hired seasonal workers to work on their farms. Roberts concluded that some local farm income was needed to attempt to migrate to the U.S., and that incomes in Oaxaca were too low to undertake migration to the U.S., so that young people from Oaxaca migrated to Mexican cities where they had contacts (1982, 319). However, a significant number of U.S.-bound migrants originated from Guanajuato, an area in which Mexican farm incomes were considerably higher.

Mines (1981, 1984) and Mines and de Janvry (1982) reviewed the evolution of migration from Las Animas, Zacatecas, a village of 1,300 in the late 1970s about three hours north of Guadalajara. Mines interviewed 67 households in Las Animas in 1979, plus additional Las Animas residents in the U.S., and found that over half of the village's income came from remittances sent home by persons employed in the U.S.

Mines concluded that Las Animas had reached a "migratory equilibrium" in 1979—the population of the village remained stable, as a result of many young residents leaving for the U.S., and many settling abroad—half of the village's residents in the U.S. were legally present in 1979, before the U.S. legalization program (1982, 446). Mines found that many of the workers older than 40 illegally shuttled between homes in Mexico and seasonal farm jobs in the U.S., while many of the younger workers were legally working in the U.S., and became less and less likely to return every winter to homes in Mexico.

Mines and Massey (1985) used migration patterns in Las Animas and another community to describe how migration networks mature. In both communities, men began to leave for U.S. jobs in the 1920s, and then migration stopped in the 1930s. Migration began again with *bracero* recruitment in 1942. The percentage of men going to the U.S. illegally increased until 1954-55, when a combination of "Operation Wetback" in the U.S., and the expansion of the Bracero Program, shifted the balance back toward legal but seasonal migration to the U.S. However, illegal immigration increased again after a severe drought in 1957.

By the 1970s, this migration network had matured, in the sense that a "sister" community was established in south San Francisco. As the Mexicans settled in the U.S., Mines observed that "cost[s] to the receiving area [California] increase and benefits decline" (1982, 452). On a visit to Las Animas in 1987-88, Mines observed that most of the young men seemed to have left Las Animas to try to qualify for the SAW program, even though most had not done the qualifying U.S. farm work in 1985-86.

Dinerman (1982) interviewed migrants and stay-at-homes in two similar Michoacán communities in the late 1970s and early 1980s, but she found that the "rate and frequency of U.S. migration were much higher" in one community than the other (1982, 42). Although both communities sent *braceros* to the U.S. in roughly equal numbers, migrants from one community had, by the early 1970s, shifted to nonfarm U.S. employment, and hired workers in Mexico to tend their plots. In the other community, fewer ex-*braceros* owned land, and more ex-*braceros* migrated within Mexico, until government support for handicraft activities created local job opportunities.

Taylor (1992, 194-5) interviewed 61 households in one village in 1983, and re-interviewed 55 of these households in 1989, and observed that the average income of sample households rose far more, from $1,800 to $3,600, than did average remittances, from $800 to $1,100. Taylor attributed sharply rising incomes to local economic activities that were made possible in part by the investment of remittances, primarily in cattle.[35]

Comparative Community Studies

As the number of studies multiplied, several authors compared the findings of community studies. There were two major approaches; to examine individual community studies, including the studies summarized above, or to focus on larger bodies of data, especially the MMP data summarized below, and to draw inferences from data collected from a number of communities with a fairly standard survey instrument.

Perhaps the most cited set of community studies are those done by Massey, Alarcon, Durand, and Gonzales in *Return to Azatlan* (1987). This book was built around extensive interviews in four communities. It concluded that the integration of the southwestern U.S. into the national economy in the late 1800s created a demand in the U.S. for Mexican labor, the restructuring of Mexican agriculture created a supply of workers willing to migrate, and the railroads provided the link between U.S. demand and Mexican supply (1987, 39).

Return to Azatlan makes four points about the process of Mexico-U.S. migration. First, few Mexicans migrated from these communities before the 1950s and, when they did migrate, they were as likely to move within Mexico as to migrate (illegally) to the U.S. Second, Mexican migration to the U.S. was almost stopped in the 1930s, as a result of the Depression and repatriations.

Third, Bracero Program recruitment began significant U.S.-bound migration after 1942, and this migration continued at roughly *bracero*-era levels after U.S.-government approved recruitment was stopped in 1964. Fourth, the share of illegal migrants among first-time U.S.-bound Mexicans dipped below 50 percent only during the late 1950s, when the Bracero Program was at its peak.

Return to Azatlan emphasizes continuity and an upward trend in a migratory process that began over 100 years ago—the significant blips in an otherwise steadily rising migration flow occur in the 1930s, when Mexico-U.S. migration slowed or stopped, and in the late 1950s, when many migrants went legally to the U.S. as *braceros*.

Other data, especially U.S. labor market data, emphasize more discontinuities in the flow. For example, studies of the U.S. farm labor market do not support the notion that a large number of ex-*braceros* came legally or illegally after 1964. In the mid-1960s, U.S. farmers were bussing workers from skid-row in Los Angeles to their farms, recruiting Indians, and asking universities to develop labor saving machines to harvest crops (Martin, 1996). Perhaps the most telling evidence that Mexican migration slowed considerably between the mid-1950s to mid-1960s was that the fledgling UFW was able to win a one-year 40 percent wage increase in 1966 from wine grape producer Schenley.

To the extent that Mexico-to-U.S. migration flows are mirrored in developments in the U.S. farm labor market, U.S. farm labor market evidence would suggest that immigration from rural Mexico to rural areas of the United States remained relatively low in the 1960s and 1970s, and then rose sharply in the 1980s. The community studies, by contrast, emphasize continuity in the migration flow—the probability of making a first unauthorized trip to the U.S., and the percentage of young men who have been to the U.S. by age 40, rises steadily, according to most community studies in west central Mexico.

Goldring (1990) noted that migrants from one community were "specialized," migrating to U.S. strawberry fields, while migrants from a nearby community migrated to the U.S. to work in construction. The mostly strawberry migrants were able to gain seniority and access to a state-run migrant camp open six months per year and offering a variety of children's and health services. Consequently, these farm worker migrants remained sojourners in the U.S., while the construction migrants settled near their U.S. jobs and sent for their families.

Cornelius (1990) studied three emigration communities in 1988—almost 600 household heads were interviewed in Tlacuitapa, Jalisco, Las Animas, Zacatecas,[36] and Gomez Farias, Michoacán. The major conclusion is that one should be "realistic" about accelerating economic development in communities that have long histories of migration to the U.S.

Mature migrant networks begin to bring immediate family members, wives and children, to join spouses in the U.S. (Reichert and Massey, 1980; Massey, Donato, and Liang, 1990; Fonseca and Moreno, 1988; Gonzalez and Escobar, 1990; Goldring, 1990; Donato, 1994). In one study, women were especially likely to make a first illegal U.S. trip by 1990, in some cases joining men who migrated seasonally for years (Kanaiaupuni, 1995). In another study, the probability that

women would migrate to the U.S. increased considerably if they had an immediate relative who received temporary amnesty as a result of IRCA (Donato, 1993).

Themes

Durand and Massey (1992) reviewed community studies, and argued that Mexico-U.S. migration evolves similarly in each community, so that "discrepancies" in factors motivating and sustaining migration are due to the "stage of migration." For example, mostly young men migrating illegally without their families for U.S. farm jobs probably indicates that the community has only recently begun to send migrants to the U.S., while women and children migrating to U.S. cities is indicative of a more mature migration stream.

Massey, Goldring, and Durand (1994), on the basis of data from 19 agrarian communities in Jalisco, Michoacán, Guanajuato, and Nayarit, concluded that although "the first international migrants tend to be married male household heads of prime labor force age, usually from a nonagricultural background and often from a property-owning class, as migration becomes more prevalent and social capital accumulates, this profile changes" (p. 1528) to include more diverse migrants. Individual characteristics lose importance over time as migration networks mature, so that even the poor, the landless, women, and children are able to also migrate, taking advantage of their community's growing migration network.

Many of the communities that have sent migrants to the U.S. for long periods have become "nurseries and nursing homes," places in which a supply of workers for the U.S. is created, and to which workers retire. Instead of trying to get experienced migrants from such places to stay home, Cornelius urges policy makers to focus on persuading "first-time" migrants to stay in Mexico, a goal that "will be difficult but not impossible" (1990, 90).

Massey (1988, 408) argued that Mexico-U.S. migration is too well developed to reduce or stop; "it is much too late in the process to have any realistic expectation of markedly affecting the level of Mexican emigration to the United States," so that migration-avoiding policies should concentrate their efforts outside of traditional migrant-sending areas. Cornelius disagrees, noting that population growth continues in traditional sending areas, and that there is some in-migration to some emigration communities to fill the vacuum left by departing migrants, so that the number of migrants even from traditional sending areas could remain large (1990, 91).

These studies raise two questions:

1. How sensitive are migration flows to socioeconomic conditions and government policies in the U.S. and Mexico?
2. Do migration flows become more or less sensitive to socioeconomic conditions and policy changes over time?

Most studies based on interviews with Mexicans in Mexico conclude that U.S. control policies have few effects on the migratory flow and that migration is becoming less sensitive to socioeconomic conditions over time.

The MMP data, for example, stress the importance of "social capital" rather than economic variables in initiating the migratory flow, and emphasize that migration flows become less sensitive to policy changes over time. For example, Donato, Durand, and Massey (1992) conclude that the probability of making a first trip to the U.S. has been increasing in the 1990s despite IRCA and stepped up border enforcement. Their data, based on 1987-89 interviews with 1,350 households in 7 communities in Jalisco, Michoacán, and Guanajuato, led to the conclusion that stepped up border enforcement and employer sanctions, which were applied to all U.S. employers as of December, 1, 1988, were not deterring especially experienced migrants from attempting illegal entry. In some communities, 100 percent of the experienced migrants intended to return to the U.S.[37]

Other community studies also suggest that IRCA did not reduce overall levels of illegal migration (Gonzalez and Escobar, 1990; Massey et al. 1990). One study of three emigration communities in Jaliso, Zacatecas and Michoacán found instead that IRCA "augmented the flow of migrants... through legalization programs." At most, IRCA may have "cause[d] a recomposition of the migrant flow" in the short run, because fewer Mexican were entering illegally (Cornelius, 1990, 23).

Studies based on apprehension data, on the other hand, suggest that IRCA was a U.S. policy instrument that reduced the influx of illegal Mexican migrants (Bean et al. 1990; White et al. 1990). Apprehension data analysts noted that much of the drop in apprehensions was due to the legalization of over 2 million Mexicans (Espenshade, 1990).

In an attempt to understand trends in apprehensions, Massey and Singer (1995, 18) used MMP data to estimate that the probability of apprehension on an illegal attempt to enter the U.S. was 0.35. By their reckoning, over the 25 years between 1965 and 1990, some 36.5 million Mexicans entered the U.S. illegally, and 5.2 million illegal Mexican residents were in the U.S. in 1989. This suggested to them that the probability of apprehension "was drifting downward" in the late 1980s—that U.S. border had become "increasingly porous." Singer, Durand, and Massey (1996, 37) concluded that "interlocking processes of social and human capital accumulation build a self-feeding momentum into the migration process... [that] U.S. enforcement practices in no way halt—and in many ways encourage."

There is also disagreement among analysts about the effects of a peso devaluation on emigration. Some, including Jorge Bustamante, argue that devaluations reduce emigration sharply in the short-run, because the cost of being smuggled into the U.S. is fixed in dollars and the smuggling fee is paid in Mexico from Mexican savings, so that a devaluation raises a financial hurdle for potential migrants.

However, if the cost of entering the U.S. is paid by U.S. residents, then a devaluation that increases the value of U.S. work relative to that in Mexico can stimulate migration. Taylor (1995), for example, estimates that a 10 percent peso devaluation increases Mexico-to-U.S. migration by 17 percent.

MMP data suggest that illegal migration was lower in 1983 and 1988, just after devaluations, supporting Bustamante. However, Donato, Durand, and Massey (1992) emphasize that the slowdown in illegal immigration was short-lived—well before the peso recovered, emigration increased.[38]

Mexico has had major devaluations at the end of each of the last 4 Presidencies; in 1976, in 1982, again in 1986-87, and in 1994-95. After each devaluation, illegal immigration as measured by apprehensions in the U.S. increased, but there seems to be no immediate and consistent relationship between peso devaluations and illegal immigration to the United States.

For example, after the 1982-83 peso devaluation, it took about 16 months for the U.S. Border Patrol to notice a significant increase in illegal immigration. In 1987, apprehensions dropped despite a devaluation of the peso, largely because so many Mexicans were becoming legalized U.S. immigrants under the 1986 Immigration Reform and Control Act (IRCA).

The drop in apprehensions in the mid-1980s despite the peso devaluation emphasizes the importance of U.S. policies in determining whether Mexicans respond to economic crisis by emigrating. IRCA was signed into law in November 1986, and for the next six months, internal INS enforcement was suspended—unauthorized aliens who could get into the U.S. were not subject to INS raids or employer sanctions.

Beginning on May 1, 1987, the U.S. offered legalization to illegal alien farm workers, and over 800,000 Mexicans took advantage of it to become legal U.S. immigrants. There was less need to risk apprehension when legalization applications could be filed in Mexico, or Mexicans could come to the border, assert that they qualified for legalization but had no records to prove that they had worked illegally in U.S. agriculture, and then obtain 90-day entry and work permits.

Smuggling fees dropped as Mexicans entered legally, and the fraudulent document industry boomed. Most applicants for legalization under the special agricultural worker (SAW) program submitted only letters from U.S. labor contractors and farmers that asserted, for example, that "Juan Gonzalez picked tomatoes for me for 92 days between May 1985 and May 1986." By some estimates, over half of the 1.1 million aliens legalized around the U.S. under the SAW legalization program were not eligible.

The economic outlook in Mexico and U.S. responses to the first two peso devaluations provide clues to the response to the 1994-95 devaluation. The 70-percent peso devaluation of 1982-83 lowered real wages in urban areas, and put

Mexican farmers in a cost-price squeeze, but the fact that most Mexican workers kept their jobs and saw their standard of living erode only gradually helps to explain the delayed illegal emigration response (Lustig).

The 1986-87 peso devaluation, by contrast, occurred when the U.S. was offering amnesty to illegal immigrants, the INS was educating employers rather than enforcing sanctions, and the U.S. and California enjoyed a period of rapid U.S. job growth, all factors that encouraged a seemingly "legal" migration response.

The 55 percent peso devaluation of 1994-95 occurred in a different climate in Mexico and the United States. In 1995-96, many Mexican firms laid off workers, rather than simply allowing their wages to be reduced by inflation. The number of workers in formal employment—permanent Mexican Social Security Institute or IMSS beneficiaries—fell by about 400,000 between mid-1994 and the end of 1995, from 8.8 to 8.4 million—estimates of the total number of Mexicans who lost their jobs in 1995 range up to 1.7 million.

Assessment

This section reviewed leading studies of Mexican emigration communities to determine what factors initiated and sustained migration to the U.S. The community studies lead to several conclusions:

- Most researchers identify U.S. recruitment, in the 1942-64 *bracero* era, as the key factor that unleashed "mass" migration to the U.S. For this reason, most of the "pioneer" migrants were young men from rural areas coming to work on U.S. farms. In most studies, a combination of stepped up U.S. enforcement and an expanded Bracero Program in the mid-1950s reduced illegal immigration and increased legal migration.
- The studies differ on what happened after the Bracero Program ended in 1965. Some emphasized that, in the late 1960s, only those who had greencards could easily enter the U.S. and find work. Other studies emphasize continuity in the migration process.
- All studies agree that, by the late 1980s, the probability that a young man would make a first trip to the U.S. was rising, that more women and children began to migrate to the U.S., and that factors other than a specific economic event—such as a U.S. recruiter or a drought in Mexico—motivated especially young men and women to migrate to the U.S.

This last finding—the changing reasons why Mexicans migrate to the U.S.—is perhaps most important for thinking about the policy responses to the changing factors that sustain Mexico-U.S. migration. The community studies suggest clearly that U.S. recruitment in the 1950s stimulated Mexico-U.S. migration. If Mexico

and the U.S. wants to avoid initiating and sustaining Mexico-U.S. migration, this conclusion suggests that U.S. recruitment of Mexican workers should be avoided.

Given current role of supply-push and network factors in sustaining migration between Mexico and the U.S., the community studies are much less clear about how to reduce or reverse sustaining factors. Only a few of the studies suggest doing nothing—that economic development stimulated by remittances in Mexico will "naturally" reduce emigration pressures, although Taylor (1992) approaches this conclusion.

More common is the conclusion of Cornelius; a "culture of outmigration" has developed in some areas of Mexico so that "migration to the U.S. becomes a complete substitute for local economic activity," despite the fact that many young migrants "have no apparent necessity for going" to the U.S. (1990, 77). Massey et. al (1987) similarly conclude that migration has become a way of life in come communities in west central Mexico, so that dramatic economic improvement in Mexico, or much tougher U.S. immigration controls, would be necessary to break the culture and bonds that have evolved.

Massey argues economic improvement or effective controls are unlikely to slow migration from established areas; "it is much too late in the process to have any realistic expectation of markedly affecting the level of Mexican emigration to the Untied States," so that migration-avoiding policies should concentrate their efforts outside of traditional migrant-sending areas, and give up where migration networks are established. Cornelius disagrees, noting that population growth continues in traditional sending areas, and that there is some in-migration to some emigration communities to fill the vacuum left by departing migrants, so that the number of migrants even from traditional sending areas could remain large (1990, 91).

The central finding of the more recent community studies is that the probability of taking a first trip to the U.S. has been rising:

- despite employer sanctions and stepped up border enforcement,
- and in part because of legalization and family unification policies.

The question is, what policies should be pursued to reduce the factors that seem to be sustaining Mexico-U.S. migration? There are at least three broad options; stepped up U.S. border and interior controls, free trade and other growth-accelerating policies in Mexico, or learn to live with high levels of Mexico-U.S. migration.

The U.S. has already stepped up U.S. border and interior controls, and is adding both Border Patrol agents and interior inspectors. There are several more notches of enforcement that could be tried, including the phasing-in of a counterfeit-resistant work permit, effective enforcement of employer sanctions and, to the extent that social services sustain some migration, more rules and screens to prevent

immigrants and unauthorized migrants from participating in tax-supporter programs.

Social service screens are controversial, since it is not clear what role welfare and other tax-supported services play in stimulating migration. Excluding unauthorized children from K-12 education, for example, may not deter unauthorized immigration, but may be counterproductive to keep unauthorized children out of public schools, making them less productive workers in the U.S. or in their countries of origin.

In any event, if the community studies are correct, neither border controls, nor employer sanctions, nor social service screening, is likely to be effective.

Most U.S. and Mexican observers believe that the best way to reduce the importance of the factors that sustain migration is to accelerate economic and jobs growth in Mexico, and to assure that the benefits of more rapid economic growth are shared widely. Former Mexican President Salinas argued for the North American Free Trade Agreement (NAFTA) on the grounds that it would accelerate job growth in Mexico, and "more jobs will mean higher wages in Mexico, and this in turn will mean fewer migrants to the United States and Canada. We want to export goods, not people" {quoted in Bush letter to Congress, May 1, 1991, 17).[39] U.S. Attorney General Janet Reno made the same point: "We will not reduce the flow of illegal immigration until these immigrants can find decent jobs at decent wages in Mexico" (San Diego Union-Tribune, November 14, 1993, 1).

Most analyses concluded that NAFTA is the policy most likely to speed up economic and job growth in Mexico and thus deter illegal immigration, even though most researchers echoed the conclusion of the U.S. Commission for the Study of International Migration and Cooperative Economic Development; "The economic development process itself tends in the short to medium term to stimulate migration" (Cornelius and Martin, 1993, Martin, 1993). After a 10 to 15 year "migration hump," these researchers suggest that Mexico-U.S. migration should decrease.

The most troubling community studies are those that, following Massey and Espinosa (1995), downplay the importance of economic variables in sustaining migration, argue that control policies cannot work, and stress the role played by "social capital"—friends and relatives who can help Mexicans to migrate to the U.S. Massey and Espinosa used interviews with 3,700 people in 25 Mexican communities to conclude that migration is increasingly motivated by "social capital theory" and "the new migration theory" rather that wage and unemployment differences that might be reduced by economic and job growth.

These studies are troubling because, if Mexico-U.S. migration really is "self-feeding," as Massey and Espinosa suggest (1995, 14), then the most effective short-run techniques to reduce or reverse the factors that sustain Mexico-U.S. migration

would be a control-style response to unwanted Mexico-U.S. migration—a wall along the border, and a moratorium on legalization and immigration. It may be that even these control efforts would be ineffective but, if economic variables do not affect flows, and social capital does, then controlling immigration rests on "decreasing" the amount of social capital available, and preventing the formation of additional social capital.

Mexican Migration Project Data Re-Analysis

The MMP data were collected in the 1980s and early 1990s from about 200 households in each of 39 communities in west central Mexico, the region of Mexico centered on Guadalajara from which most Mexican migrants to the U.S. have come (Mexican Migration Project, 1995). The communities range in size from 1,000-person hamlets in 1990 to a section of Guadalajara, a city with a 1990 population of 2.9 million. As of 1993, the MMP data included information on about 42,700 men, women, and children, including 9,530 migrants.

In each of the 39 communities, about 23 percent of the housing units were randomly selected after a house to house census established the total number of housing units, and household interviews were conducted in December-January, when sojourner U.S. migrants often return to Mexico. Individual migration histories were compiled for all members of the household, including children of the household head who had formed their own households, and those absent when the interview was conducted; information was gathered on an average 9 persons per surveyed household.

Interviewers spoke with the household head and obtained information on all children, whether they were present or absent and, if absent, whether they were in Mexico or the U.S. (Massey and Espinosa, 1995, 4). For the household head, a "migration history" was compiled for each year after age 15—did the person migrate to the U.S. and, if yes, as a legal or illegal migrant. In addition, interviewers talked to about 20 migrants from each of the communities in the U.S. the following summer to obtain data on e.g., U.S. wages and remittances.

Modeling First Migrations

This section presents the results of models that predict the probability that a young man aged 20 to 24 would migrate to the U.S. in any year, and the cumulative probability that young men would take a first trip to the U.S. by age 40. For each year of life, a household member being interviewed had three choices (1) not migrate to the U.S.—coded 0—or (2) make an unauthorized trip[40]—coded 1—or (3) migrate lawfully—coded 2. Once a person migrated, that person was excluded from further

analysis, so that every year, both the numerator and denominator changed, as some people migrated, while others turned 20.

These individual life-histories were used to estimate "age-period" models of migration, i.e., the ages of residents and community characteristics were assembled to estimate the probability of migration to the U.S., and whether the first trip was legal or illegal, for each year after 1940. Two probabilities were estimated:

- the probability that a man aged 20 to 24 migrates to the U.S. legally or illegally in a given year
- the cumulative probability that men by age 40 would have made a first legal or illegal trip to the U.S.

The typical person for whom "first U.S. migration" behavior was modeled was a 32 year old married man, with about 5.5 years of education and 2.2 minor children at home (Massey and Espinosa, 1995, 8). Across these MMP communities, about one-third of the men made a first trip to the U.S. by age 40, although in six of the 30 communities, over half of the men made a first U.S. trip by age 40.

For example, in community 2, a section of a large city, the probability that a young man 20 to 24 would migrate illegally to the U.S. was 1 percent in 1994, and 16 percent of the young men in this section of the city would migrate illegally to the U.S. by age 40 (Table 2).

To better trends over time, consider a typical community—say number 11, with a 1990 population of 20,000. Table 4 shows that about 12 percent of the men aged 20 to 24 in this community took a first illegal trip to the U.S. in 1980. About one in 10 young men continued to make a first illegal trip to the U.S. from this community throughout the 1980s—the low point in illegal migration was in 1993, when only 3 percent of the young men made a first illegal trip. The probability of an illegal first trip more than doubled to 7 percent in 1994, which means that 7 of 100 young men in community 11 made a first illegal trip to the U.S. in 1994.

Braceros were recruited in community 11, and the first-legal-trip data indicate that, during the *bracero* era, 1942-1964, about 2 percent of the young men made a first legal trip to the U.S. However, there was also considerable illegal immigration—there were only two periods during the *bracero* era when first legal trip probabilities were greater than first illegal trip probabilities—1940-44, and 1955-59.

In the early 1980s, three times more young men made their first trip to the U.S. from community 11 illegally than legally. However, in 1988, more young men went legally than illegally, and the legal probability has generally exceeded the illegal probability since.

Many U.S.-bound migrants are from very small places that, even in 1990, had only 1,000 to 3,000 residents. For example, Community 10 is typical of the small villages that depend on emigration and remittances to supplement earnings from rain-fed agriculture.

According to migration histories collected in 1989 from 150 households in Community 10, in the early 1940s, about 3 percent of the young men made a first unauthorized trip to the U.S., and 6 percent made an unauthorized trip in the early 1950s. First unauthorized trips slowed in the early 1960s, but then jumped in the 1980s, so that, between 1984 and 1986, over 40 percent of the young men who had not previously migrated made a first unauthorized trip to the U.S. Community 3 has similar first illegal trip probabilities, peaking at over 30 percent between 1984 and 1986.

The figures in the Appendix show that the probability of making a first illegal trip to the U.S. from communities 10 and 3 was higher than the probability of making a first legal trip from 1971 through 1987. Since 1987, more young men are making their first trips legally rather than illegally. In community 3, note that the chance of an illegal first trip remained higher than a legal trip throughout the 1971-94 period.

The cumulative probability data estimate how many young men from a community would have taken a first trip by age 40, legally or illegally. The pool of those who could migrate—the denominator—is all men in the community under age 40 who have so far not migrated legally or illegally.

During the wartime Bracero Program, 1942-46, the cumulative probability of migration legally was considerably higher than for illegal migration. However, in the late 1940s, the probability of illegally migrating exceeded the probability of legal migration, but legal migration once again became the norm after Operation Wetback in 1954 until the end of the Bracero Program in the early 1960s.

After 1964, the cumulative probability that young men migrated legally trended downward, while the cumulative probability of a first illegal trip moved up, peaking at 80 percent across these emigration communities in the early to mid-1980s. After reaching a low in 1985, the cumulative probability that a young man would have made a first legal trip to the U.S. by age 40 has fluctuated, with legal and illegal cumulative probabilities following the same patterns.

Women have different migration patterns than men. A woman's chance to migrate legally is generally higher than her migrating illegally, and women are most likely to migrate during periods of family unification, the mid 1960s and the 1990s. But from some communities, such as 3, women's migration patterns are similar to men's—the probability of migrating illegally is always higher than migrating legally throughout the 1971-1994 period.

Assessment

Based on the model and the MMP data, it appears that the probability of young men leaving west central Mexico for the U.S. by age 40 was 80 to 90 percent since the early 1940s. On a year by year basis, the major difference was whether young men made their first trips legally or illegally.

In the early 1940s, about two-thirds of the young men in the 39 communities took a first legal trip to the U.S. by age 40, and another 25 percent took a first illegal trip. Over the years, legal and illegal probabilities mirror each other—when the probability of a first legal trip decreases, the probability of a first illegal trip increases, ensuring that 80 to 90 percent of the young men make a first U.S. trip by age 40. There are two exceptions to this pattern—in the mid-1960s, and again after 1987.

The migration data from these 39 communities provide evidence that, from traditional emigration areas of Mexico, the U.S. policy choice is whether young men take their first trips legally or illegally, i.e., U.S. and Mexican economic conditions and policies seem only to shift migrants between legal and illegal categories. However, the data and analysis leave several questions unanswered, including whether and how U.S. and Mexican economic conditions and policies change the duration of stay abroad, and whether and how migrants who return to Mexico attempt re-entry.

New Community Studies

The mid-1990s represent a new era in Mexico-U.S. migration. There are several reasons, including changes in U.S. immigration law and enforcement practices, the implementation of NAFTA, and the restructuring of the Mexican economy. In order to determine how these and other changes are affecting Mexico-U.S. migration, we commissioned four new community studies for this report.

Themes

The community studies completed in 1995-96 reach several conclusions;

1. First, they agree that, although economic factors remain central to the decision to migrate, the factors initiating and sustaining Mexico-U.S. migration have become more complex. Most Mexican research on the factors that initiate and sustain migration include economic, social, geographic, environmental, and other factors (Stern 1977, Arizpe 1978, Winnie and Arroyo 1979, Lopez 1986, Gonzalez and Escobar 1990, Arroyo 1994, Arroyo and Papail 1996), but not in a manner that attempts, e.g., to assert the relative importance of each of these factors.

2. The new cases studies emphasize that there are network turning points which can be obscured in retrospective migration histories. Two examples make the point. First, Mexico City changed from the major destination to the major origin of Mexican migrants between 1970 and 1990, yet network studies failed to find network tipping points related to economic, environmental, and social variables that would explain the change.

   Second, there is universal agreement that more women and children are joining husbands in the U.S. in the mid-1990s. There is little agreement on why Mexican women apparently decided that it was better to raise their children in the U.S., and that Mexican men and women decided that, with two earners, they could survive better in the U.S. than Mexico.

3. Our mid-1990s interviews find that the probability of successfully entering the U.S. on a first unauthorized attempt is rising, to 59 percent in 1994-95. Almost two-thirds of first time migrants are using coyotes to help them cross.

Evolution

Most of the community studies of emigration areas in Mexico before the mid-1980s were done or supervised by U.S.-based researchers. Massey and his three Mexican anthropologist collaborators—Alarcon, Durand and Gonzalez—cast a long shadow in both countries. These researchers popularized the network concept on both sides of the border, and emphasized the importance of "social capital" in migration decisions.

Mexican researchers in the 1970s and earlier examined internal migration, and used concepts such as networks to explain the movement from rural to urban areas. For example, Arizpe examined "relay migration" from impoverished indigenous regions to Mexico City (1975, 1977), and Lomnitz studied social networks in a small migrant community (1975, 1977). Both showed how the decision to migrate depended on personal contacts—"microstructures of migration" or networks—how migrants from the same community or family grouped together in their destination, and often practiced the same trades or entered the same businesses, and how mutual assistance led to the formation of new urban communities based on groups, values and cultures that the migrants brought with them.

Mexican community studies today pay deference to networks, but lay more weight on economic factors such as employment, poverty, and wage gaps than do the studies linked to Massey (Orozco 1993, Arroyo and Papail 1996). Mexican researchers also put more weight on non-economic and non-network factors, such

as distance from the border or destination community, community organization, kinship and ethnic characteristics.

A typical Mexican study is that of Margulis and Tuiran(1986), which stresses that there was an uneven distribution of capital and labor across space, and that migrants were searching for survival and better opportunity. The demand for migrant labor in the U.S. is considered an important factor after 1900, and became especially important after 1940. Indeed, Margulis and Tuiran argued that the U.S. used the *bracero* system to take advantage of Mexican labor when it was most productive, and not bear its upbringing or retirement costs.

Network reasons for initiating and sustaining migration have been a mainstay of the Mexican literature since the 1980s. There are two approaches to networks. First, some researchers see networks as a channel that facilitates migration and lowers the cost of a risky undertaking. In this sense, a network is a kind of social organization that structures migrants' experiences, and provides substantial help to migrants, precisely because it is "open" to helping relatives, friends, and members of the community (Lopez 1986, Alarcon 1989, Durand 1988, Rionda 1992).

The second approach to networks is to see them as bridges that link a single community across space. In this binational community view, economic concerns, politics, religion, ethnicity and identity are similar in the linked communities, laying the basis for mutual support despite distance (Lopez 1995, Espinosa 1996, Mummert and Zendejas 1996, Durand 1992). Many researchers combine both approaches, seeing networks as both open social structures, and as the glue binding binational communities together.

The fact that networks have become an umbrella concept that encompass a great deal of human behavior tends to obscure certain features that are vital to initiating and sustaining migration. For example, so some families and individuals profit differentially from existing networks, perhaps by "placing" members in crucial points, or should a network be viewed as a big and happy family? More refined analyses are needed to determine when and how networks break up; when and how individuals decide to migrate in spite of weak or no links to networks ; and when and how a "binational community" reconstitutes itself in the U.S., as when most women and children join men abroad.

History shows that migrant destinations change, yet network theory has been unable to explain why. For example, between 1970 and 1990, Mexico City switched from being the major destination for Mexican migrants—far more important than the U.S.—to becoming the major origin for migrants in Mexico. However, network studies provided few clues as to how such a major shift could occur so quickly, although the major variables—fewer jobs, high housing and living costs, environmental factors, and social fears such as crime—probably reversed networks with ever-more social capital within 20 years.

One key variable in network breaks is family—when and why do wives and children join men in the destination area? It is clear that more Mexican women and children are migrating to the U.S. possible (Gonzalez de la Rocha 1989, Mummert 1996 in appendix, Lopez 1996 in appendix), but it is not clear whether the return to nuclear families in one place represents a significant change in gender relations, or a return to a situation of protection by the male.

The community studies commissioned for this report suggest that two factors are at work. First, more women seem to have decided that it is better to raise their families in the U.S., where children can complete secondary school. Second, many men apparently want the U.S. earnings of their wives to support themselves in the U.S.

The body of research based on interviews in the late 1980s of the past 40 years of migration cannot easily locate such "turning points" in migration networks. However, the new case studies suggest that a combination of economic instability since 1982, slow job growth, and restructuring that promises little economic future in some emigration areas certainly played a role in the decision to move to the U.S.

In addition to network turning points, the new case studies indicate that a rising percentage of unauthorized migrants are entering the U.S. on their first attempt. Based on interviews with 1,200 households in Jalisco in 1995-96, about 48 percent of those attempting illegal entry into the U.S. succeeded on their first try in 1980-84, 53 percent between 1985-93, and 59 percent in 1994-95. Reliance on coyotes also increased—50 percent of those attempting a first illegal entry used a coyote in 1990-93, versus 71 percent in 1994-95, and more migrants are attempting entry in Mexicali-Nogales.

Key Informants and Public Opinion

In early June 1997, key informants in west Central Mexico were asked about the extent, effects, and likely future patterns of emigration. Three themes dominated their responses:

1. Most migrants from central Mexico to the U.S. are rural, not urban residents. Many live in small "bedroom" communities that have less than 5,000 residents, and are dependent on rainfed agriculture and urban and farm jobs in nearby towns. Most key informants emphasized that the choice is occasional work in Mexico for 22 to 24 pesos ($3) per day in rural Mexico, or minimum wage work in similarly uncertain labor markets in the U.S.

2. There is a culture of emigration, in the sense that many rural young men expect and are expected to migrate to get the money needed to buy a

house and marry. In other words, going and coming to the U.S. is such an everyday occurrence that someone with a U.S. network who does NOT go is considered the exception. Despite much discussed stepped-up U.S. border controls, and a great deal of misinformation about IIRIRA e.g., barring illegal alien children from U.S. schools, several key informants noted that it takes only 1 successful entry and return with money to offset 100 failures and induce more young men to make the trip.

3. The most surprising finding was that many key informants who seemed knowledgeable about migration stressed the NON-importance of remittances in launching local businesses, especially larger businesses that employed 10 or more workers. Indeed, even returned migrants with successful businesses stressed that they got the money to begin the business in Mexico, not in the U.S. All acknowledged that the spending of remittance money on food and housing has local multiplier effects on economic activity, and that some remittance savings were invested in agriculture, but we were struck by the inability of key informants to mention by name a local business success that was founded by a returned migrant with remittances, while all knew of the handful of multinationals such as Nestle that had operations in the area.

Key Informants

This section provides capsule summaries of several of the places that were visited. All were in Jalisco, the largest state in west central Mexico, and a place were agriculture means that farmers with a few hectares of land plant corn in mid-June, and hope that enough rain falls in the summer so that there is a harvest in October-November.

Zapotlanejo, about 20 minutes east of Guadalarja, Jalisco, is a city and municipality of 80,000 that represented the optimistic end of the development-slows-emigration spectrum. This “birthplace of the clothing industry” has 1,400 small retail shops selling a wide range of sports-oriented clothing for children and adults. The city of 47,000 has grown rapidly, as rural residents abandon farming and move into shanty towns on the edge of the city—at least 5,000 people in Zapotlanejo live without water or electricity. The 33,000 rural residents in the surrounding area, everyone agreed, are suffering from low farm prices and high costs of producing crops; some farm land is reportedly being abandoned.

Men began migrating to the U.S. from Zapotlanejo in the 1940s under the Bracero Program and illegally, but there was a sharp increase in emigration in the late 1960s, when many residents were able to obtain green cards from U.S. employers

and work in the U.S. as greencard commuters. Today, there are ex-Zapotlanejo residents settled in California, Chicago, and Texas; one estimate was that about 80 percent of those who worked in the U.S. stayed.

Zapotlanejo has experienced a boom in the past 10 years, as the number of retail clothing shops expanded by over 100 each year, reflecting its reputation for quality production. An estimated 5,000 local residents are employed in the clothing industry, and others are employed in support industries, including transport (2,000 visitors reportedly arrive every day). However, this still leaves 10,000 or more workers in the region—many on farms—who are unemployed or underemployed.

One such migrant was a father of 10 who worked most of each year in a Dallas factory, and who had at least one son working in Tennessee illegally. This farm family with 11 cows had several children who completed high school and went to college, as well as a newly-established retail clothing shop, but when asked how many of the children would go if there were a new guest worker program that offered legal entry and work permits, the mother thought that most or all of her children would go. The father reportedly goes into debt to farm in Mexico, and migrates to the U.S. to earn money to pay off the farm debts.

Perhaps the central migration issue in this town is the race between the U.S. and the clothing industry to absorb workers. Despite high wages—$400 to $500 per month for the men who cut fabric, and $250 per month for the women who sew at piece-rate wages, there seems to be a combination of shortages of skilled and experienced workers for the clothing industry, and too many rural workers going into debt in agriculture. In an area where the minimum wage is 22 pesos or $3 per day, we were told that all workers expect to be paid more than the minimum wage of 22 pesos per day ($3).

It is expensive to set up a sewing shop in Zapotlanejo; little commercial space is rented, but if it were, 700 square meters of space to establish a sewing shop would rent for 2,000 pesos or $250 per month, and sell for $60,000—real estate prices may have tripled in the past 10 years in Zapotlanejo.

Most shops that have sewing machines buy rather than rent them, and establishing a sewing shop with 10 sewers can easily cost $10,000, including sewing machines at $600 each. In addition, larger sewing shops in town are subject to social security or IMSS taxes that add 25 to 30 percent to wages. But key informants said most sewing shops started with one or two machines in a home that could be bought with less than $1,000, and used family labor to get established (usually the cutting was done in larger factories, who also paid for the fabric, and home workshops only did sewing for them). Over time, these home-based workshops expand or cease to exist.

The goal of the town is to decentralize sewing, to lend sewing machines to rural women, and to have them sew garments in their homes. This would prevent the growth of shanty towns around Zapotlanejo, and help sewing shop owners to avoid IMSS costs. IMSS are social security and other payroll taxes that add approximately 20 to 30 percent to wages.

While the decentralization of sewing might provide more jobs for local women, it is not likely to provide many additional jobs for local men in rural areas, who are most likely to emigrate. About 20 percent of the farm land around Zapotlanejo is in ejidos, and land prices seem to vary considerably, from $3,600 per hectare for dryland crop land. There is a local dairy industry, but everyone agreed that milk prices were too low to make milk production profitable.

There is one American firm in Zapotlanejo, employing 250 seamstresses; it received a special municipal tax break to locate there. It does all its sewing in the shop, pays all labor and employment taxes, and exports garments to South America and U.S. markets.

Pegeuros is a town of 4,000, plus 4,000 in the surrounding countryside, that has a long tradition of emigration. The local economy is based on rainfed agriculture, but has developed a significant agribusiness industry centered on poultry, dairy, and hogs; these agribusinesses developed in Pegeuros because their owners were from the area, not because the area has either cheap animal feed or slaughtering facilities. Some key informants reported low wages of $25 to $40 per week for laborers were also a factor in the decision to locate in Pegeuros. Both large-scale dairy and poultry production are reportedly profitable.

The returned migrants in Pegeuros stressed the non-importance of remittances and skills acquired in the U.S. in starting local agribusinesses. Instead, they credited e.g., selling clothes in Mexico City with laying the foundation for local agribusinesses. Several noted that the amount of money needed to begin a viable agribusiness greatly exceed what a typical migrant can earn while in the U.S., so that most remittances are spent on current consumption and improved housing. Ironically, many of the workers employed for wages in these local agribusinesses are migrants from nearby towns, since Pegeuros residents tend to go to the U.S., or expect U.S. wages in Pegeuros (supervisors and accountants on large farms earn $400 to $500 per month).

There are as many persons born in Pegeuros in the U.S. as in Pegeuros, and some have been very successful, including several who started businesses in the Los Angeles area. The U.S. Pegeuros-residents have a club that returns money to Pegeuros for civic improvements, but some of the projects supported by the club have not benefited local residents, including a clinic that was built with club support in 1995, but in 1997 had no equipment because Mexican customs refused to

allow the entry of donated medical equipment. The U.S. clubs maintain ties to their Mexican villages of origin with beauty pageants in both the U.S. and Mexico that include contestants from the U.S. and Mexico; many week-long fiestas in Mexican villages include a day for migrants living in the U.S.

A typical lot in Pegeuros on which to build a house cost $2,500, and the house another $20,000, although one house built by an extremely successful Pegeuros migrant in Hollywood cost $200,000. Many of the successful migrants who settle in the U.S. invest in real estate and businesses there; some local residents complain that those who settle in the U.S. reduce remittances and investments in their village of origin.

Pegeuros leaders feared a mass return of Mexicans after April 1, 1997, but so far, there have been almost no returns. There have been a few returned criminal aliens, and they have caused trouble, and inspired imitation by local youth.

The Los Altos area of Central Mexico has been exporting young men for centuries, for seminary and work. One village of 2,800 was mostly dependent on U.S. remittances and money earned in nearby towns—it was a "bedroom community" seemingly closer to the U.S. labor market than to local jobs that added residents despite emigration through births exceeding deaths. At least 500 persons born in the village were in the U.S.; there are also retired residents living in the village who worked in the U.S., and now receive U.S. Social Security benefits.

There is a marked contrast between public squalor and private affluence in these villages. The main street running through town was only quasi-paved, but the homes of migrants were immediately noticeable because of their satellite TV dishes. Migrant remittances were also being used to construct a fairly-elaborate hall for weddings and 15-year old coming out parties for girls.

When asked how many young men would go if there were a new guest worker program that permitted legal migration, most people expected most of the young men without education to leave for the U.S.

Lagos de Moreno is a town of 125,000 that has a long tradition of resistance to the federal government's land and other reforms. Lagos de Moreno is actually two distinct areas; a city bustling with factories that process agricultural products, including milk, and shops selling a variety of goods, and a rural hinterland that includes over 300 villages often filled with struggling farmers. The major agricultural enterprise is dairying; Nestle has a plant in the town.

Lagos de Moreno has several enterprises that send workers to the U.S. for training, but it appeared that the workers sent to the U.S. for training were not those who would otherwise have migrated.

Key informants in Lagos de Moreno spent some time discussing differences between groups of residents, including Native Americans who married among themselves, and poor blond girls who were able to marry up because of their looks. All

agreed that a root cause of rural poverty in the area was a poorly-executed land reform in the 1950s and 1950s, when haciendas were divided up among peasants, but they were not provided with the credit that the hacienda owners provided, so farm production fell. One elderly Lagos resident recounted how her husband went to the U.S. as a *bracero* in the early 1940s, and with 5,000 in peso savings from 18 months of U.S. work was able to begin what turned into a profitable cattle business.

Opinion Polls

This section presents public opinion data from 1989 and 1995 on the factors that sustain migration across the U.S.-Mexican border. The Los Angeles Times interviewed some 1835 Mexicans August 5-13, 1989 in 42 Mexican cities and towns to determine whether IRCA was discouraging illegal migration to the U.S. About one-third of the Mexicans who responded to the poll reported they had already visited the U.S., 42 percent said they had relatives in the U.S., and 7 percent reported that they received funds from a U.S. relative.

About 6 percent of those polled in Mexico in the summer of 1989 reported that they were "very likely" to take up U.S. residence in 1990, and 16 percent said that they were "fairly" likely to move north within the next year. Since each one percent of respondents was assumed to represent about 850,000 Mexican residents, this was interpreted to mean that about 4.7 million Mexicans were "very likely" to move to the U.S. illegally in 1990. These polling data were used to conclude that, despite IRCA, many Mexicans planned to illegally enter the U.S. (Marjorie Miller, "The Times Poll—Despite New Laws, U.S. Still a Lure in Mexico," Los Angeles Times, August 21, 1989).

Conclusions

Much has changed since Herbert Hoover in 1918 argued for removing restrictions on Mexican immigration by asserting that "we need every bit of this labor that we can get and... we will need it for years to come" (Quoted in Kiser and Kiser, 1979, 14). However, there has been one constant—a debate over whether Mexican workers were truly needed in the U.S. The Mexican Consul in Arizona, in 1918, noted that many Mexicans and Mexican Americans in that state were unemployed, so that "there is an abundance of labor here [in the U.S.] and what is lacking is a good wage and above all good treatment" (Quoted in Kiser and Kiser, 1979, 15).

The constants in Mexico-U.S. migration are at least threefold:

1. The pleas of U.S. employers, especially farmers, for supplementary foreign workers.

2. Arguments by U.S. unions, churches, and sometimes the Mexican government that there was no shortage of labor in the U.S., only a shortage of wages and decent working conditions.

3. Migration off the land in Mexico (Escobar and Roberts, 1996, 1).

After almost 80 years of Mexico-U.S. governmental interaction over Mexican migration to the U.S. for employment, there is still disagreement over facts, trends, and recommendations.

We believe that Mexico-U.S. migration for employment is initiated and sustained by three broad categories of factors; demand-pull factors in the U.S., supply-push factors in Mexico, and network factors that bridge the border. Our major conclusion is that the factor that initiated Mexican worker movement to the U.S.—government-approved U.S. employer recruitment—has been joined by supply-push and network factors as major motivators and sustainers of migration.

Given the importance of supply-push and network factors in current Mexico-U.S. migration flows, we argue that there is currently a peak or hump in Mexico-U.S. migration that should be reduced by economic and job growth in Mexico beginning in 5 to 15 years.

Notes

1. U.S.-Mexico migration for employment and retirement patterns are summarized in Volume 3, pages 869-1000.

2. According to Massey, 95 percent of Mexicans' first trips to the U.S. are unauthorized (1996). The INS estimated in 1997 that there were 5 million unauthorized aliens residing in the U.S. in October 1996. Of these, 54 percent—2.7 million—were Mexicans who the INS believes were residing in the U.S. 12 months or more. The number of unauthorized aliens settled in the U.S. was estimated to be increasing by 275, 000 per year, including 154,000—69 percent—Mexican nationals (INS, 1997). In addition to resident illegal alien Mexicans, there are additional seasonal or sojourner migrants who are in the U.S. part of each year—perhaps 500,000 to 1.5 million.

3. Mexican estimates suggest an increase of 277,000 legal and unauthorized Mexican-born persons in the U.S. each year, while U.S. estimates suggest 340,000 per year. Between FY91 and FY95, the 1.5 million legal Mexican immigrants were almost 30 percent of the 5.2 million legal immigrants admitted to the U.S.

The number two country of emigration, the Philippines, reported that 4.2 million Filipino-born persons were living outside the Philippines in 1996, and that 654,000 Filipino workers were deployed abroad in 1995. The Philippine Central Bank reported that remittances from Filipino overseas contract workers increased over 63 percent to U.S. $4.9 billion in 1995 (124 billion pesos), up from U.S. $3 billion in 1994 .

4. The 4 million to 5 million Mexican workers employed in the U.S. are equivalent to 40 to 50 percent of the Mexican workers permanently employed in private formal sector jobs in Mexico.

There were 9,163,459 permanent workers enrolled in IMSS at the end of 1996, a record gain of 661,024 from 8.5 million at the end of 1995, reflecting in part the return of 274,493 IMSS jobs lost in 1995. Growth continued in 1996: some 282,782 permanent workers were enrolled between January and April 1997, bringing the total to 9,446,241 at the end of April 1997, including 103,000 additions in April. Of the permanent workers enrolled in IMSS, 40 percent were in manufacturing (377,000 new IMSS jobs in 1996), 36 percent in services (166,000), 19 percent in trade (103,000), and 5 percent in agriculture (16,000).

In addition to permanent IMSS participants, some 2 million to 4 million government employees are permanent workers affiliated with ISSSTE, the government workers social security institute.

It should be emphasized that not all Mexican workers in the U.S. are in formal sector jobs. However, according to the NAWS, virtually all Mexican born farm workers have social security taxes deducted from their wages.

5. Sometimes migrants repay smuggling costs by working in coyote-related employment in the U.S., suggesting that funds to pay for entry, border crossing, and U.S. employment are becoming more closely linked

6. Based on mid-1990s fertility levels, Mexican woman average three births in a lifetime, down from seven in 1970. If lifetime fertility in Mexico stabilizes at 2.5 children per woman, Mexico's population will rise from 96 million today to 192 million in 2050, according to PRB. If lifetime fertility stabilizes at 2 children per woman, the Mexican population would be 154 million in 2050.

The secretary-general of Mexico's National Population Board predicts that Mexico's fertility rate will fall to 2.1 births per woman by 2005, and then fall below replacement level. The growth in the number of Mexicans 0 to 5 is currently zero, and the growth of the 6 to 14 age group is about 0.6 percent per year.

7. There are several measures of employment and unemployment in Mexico. A May 1995 Banamex review of data from the National Employment Surveys of 1988, 1991, and 1993 (ENE), household income and expenditure surveys of 1984, 1989, and 1992 (ENIG), and the population censuses of 1980 and 1990, concluded that the labor force or economically active population 12 and older in 1995 was 36.1 million, up from 33.7 million in 1993, and 31.2 million in 1991—in 1993, about 10 percent of the 12-14 year olds in urban areas with 100,000 or more residents were in the labor force, and 30 percent of the 12-14 year olds in rural areas (152-3). According to Banamex, Mexico had 27.4 million paid employees in 1995, and a labor force of 37 million in 1997, including those who are self employed, unpaid family workers, and the unemployed. A 1995 report from the U.S. Embassy in Mexico City estimated that 35 percent of economically active Mexicans are either unemployed or underemployed.

8. Between 1993 and 1997, Mexican National Employment Surveys indicate that the labor force increased from 32.4 million to 36.7 million, or by over 1 million or 3 percent per year. The 37 million current labor force number includes about 4 million unpaid family workers and 2 million unemployed workers; those classified as employers or wage and salary workers totaled about 30 million in 1997.

9. Even if economic growth averages 4 percent per year, the Mexican economy should be able to generate enough jobs for the smaller entry labor force cohorts after 2000. At 4 percent GDP growth, and the 1.35 economic-employment growth ratio, Mexico would be generating about 950,000 jobs per year soon after 2000, which should fully absorb the entry cohort. With 3 percent growth, and the 1.35 growth-employment ratio, Mexico should generate

800,000 new jobs per year, which should absorb the entry cohort of 2005 (Mexico's total labor force may grow by more than 800,000 per year, as persons not in the labor force seek work if jobs are available).

10. Mexican manufacturing is considered capital intensive, and with a high import content, reflecting *maquiladora* assembly activities, e.g., television parts are imported, and assembled televisions are exported. Tijuana has become the world's TV-manufacturing capital, churning out 14 million sets a year.

11. In FY95, the 19,200 Mexican non-immigrants admitted to the U.S. with H, O, P, Q, and R visas were 10 percent of the total 196,800 non-immigrants admitted with such visas, including 6,100 H-2A farm worker admissions, and 3,500 H-2B nonfarm worker admissions. Current non-immigrant temporary worker programs permit U.S. employers to recruit foreign workers anywhere.

12. It is easy to emphasize the gap between U.S. and Mexican positions, or ways to narrow the gap. For example, most U.S. employers would agree that Mexican guest workers would have to be paid prevailing U.S. wages, and work under prevailing U.S. working conditions, as Mexico would likely insist. However, U.S. farm employers have proposed that temporary foreign workers receive a housing allowance in lieu of U.S.-government approved housing, something that may be hard to justify given that the foreign workers presumably have no knowledge of local housing conditions, and that they are entering the U.S. for seasonal work.

In other words, if the seasonality that some U.S. and Mexican advocates think characterizes Mexican-U.S. migration is real, then there may be pressure to adopt different and lower housing and protection standards for guest workers, which may increase opposition to a guest worker program.

Whatever protections are adopted, many worker advocates believe that U.S. enforcement is adequate to ensure that they are obeyed.

13. There is a debate over whether low wages or unemployment is the major push factor in Mexico that encourages emigration. Massey et al. 1994, 710 conclude that "employment related variables [in Mexico] generally equaled or exceeded those of wage-related indicators."

14. Lowell (1995, 15) notes that the number of legal immigrant entries into the U.S. is (1) negatively correlated with non-immigrant entries across 116 countries that send migrants to the U.S., and (2) positively correlated with illegal entries, suggesting that legal immigration is a proxy for "emigration pressure" from a country.

15. Both historically and today middlemen recruiters and transporters have been involved in the migration process. Today, these understudied middlemen—who might be considered as arbitrageurs of differences between international labor markets—play an role in facilitating illegal labor migration, extracting a fee from migrant workers or their employers equivalent to 25 to 100 percent of what the migrant will earn in his first year abroad.

16. It should be emphasized that unauthorized workers accompany legal guest workers in every country with a guest worker program. The ratio to unauthorized to authorized workers is amenable to policy intervention, as in the mid-1950s, when the U.S. launched "Operation Wetback" and simultaneously encouraged farmers to employ legal *bracero* workers.

17. In 1947, there was a smaller than usual cotton crop, and relatively little farm work available in southern California during the winter months. However, the fall 1948 cotton crop was much larger than usual, increasing the demand for labor in 1948.

18. Some Midwestern meatpacking plants offer "bounties" of $200 to existing workers for each new worker referred. Many plants have recruiters who seek out workers within 50 or 100 miles of the plant, and some send recruiters to Texas or California in search of workers. For more details on how Mexican and other workers are recruited to work in Midwestern meatpacking plants, see Martin, Taylor, and Fix, 1996

19. Tomatoes are native to South America. Commercial U.S. production began in the 1880s. The U.S. produces about 20 percent of the world's tomatoes.

Cannery or processing tomatoes are harvested by cutting the plant and shaking off the tomatoes. The tomatoes are then sorted by color as they move past an electronic eye, and then loaded unto 25 ton trucks for delivery to processing plants.

The tomatoes are washed, screened to remove debris, and then either sliced or processed into tomato paste.

20. In addition, there were in 1993-94 about 500,000 non-immigrant foreigners working temporarily in the U.S. labor market—temporary non-immigrant workers are often found in the same sectors as settled foreign workers, viz, construction, agriculture, and hotels and restaurants.

21. The 23 million rural Mexicans shared the $30 billion rural GDP in 1994, giving them an average $1,311 each, while the 67 million urban Mexicans who shared the remaining $347 billion GDP had an average $5179 GDP each. Mexico's economy shrank by about 7 percent in 1995.

22. According to a Mexican proposal to the World Bank in 1995, 41 percent of Mexicans live in rural areas, and 84 percent of the extremely poor Mexican residents are in rural areas. Mexico-Agricultural Development and Rural Poverty Project, MXPA7711.

23. At the other end of the spectrum, Mexico includes the fourth largest number of billionaire families—24—after the U.S., Japan, and Germany. The wealthiest Mexicans in 1994 included Carlos Slim Helu ($6.6 billion in assets, Telmex), Emilio Azcarraga ($5.4 billion, Grupo Televisa), Lorenzo Zambrano ($3.1 billion, Cemex), and Aleko Peralta ($2.5 billion, Grupo IUSA)

24. About 12 percent of the sample households included an adult who had migrated to the U.S. in the past four years, and 27 percent included an adult member who had migrated to the U.S. at least once (de Janvry and Sadoulet, 1997, 7).

25. There are a few commodities that can be produced cheaper in Mexico, including avocados. However, when the USDA held hearings on whether Mexican avocados could be imported into the American northeast, where the pests common in Michoacán could not survive the winter, California producers called for keeping trade barriers in place until there was much more study and information available on the possible risks to U.S. avocados and citrus. California has 60,000 acres of avocados, and California avocado sales in 1995 were about $225 million.

26. Most Mexican vegetable exporters provide housing in 125 camps in the Culican Valley at no charge to their harvest workers, often 150 square feet for each family, which can range six to 10 family members. Government doctors visit the camps to dispense basic medicines and to teach techniques of birth control; however, the schools in the camps teach from 5 to 8 PM, so that children can help their parents in the fields

27. Helene Cooper and Bruce Ingersoll, "With little evidence, Florida growers blame tomato woes on NAFTA," Wall Street Journal, April 3, 1996.

28. For example, a Mexican peasants organization, the National Union of Autonomous Regional Campesino Organizations (UNORCA), in April 1996 asserted that more than 80 percent of Mexico's of what it said were three million ejidatarios, and 2.5 million small farmers, were vulnerable to bankruptcy. In late April, 1996, the Mexican government announced a plan to provide $1 billion in credit and technical assistance to 600,000 producers of grains on 11.5 million acres.

29. There were dozens of hearings on whether NAFTA should be approved by the U.S. Congress, but only one devoted specifically to how NAFTA would affect Mexico-to-U.S. migration. During the November 3, 1993, hearing before the House Judiciary Subcommittee on International Law, Immigration and Refugees, Chairman Romano Mazzoli (D-Ky) repeatedly asked Administration officials why they had not reached an agreement with Mexico on additional steps to control illegal immigration. They responded with variations on the statement of Deputy United States Trade Representative Rufus Yerxa: "NAFTA does not explicitly address the issue of illegal immigration, but in the long run, it is one of our best bets to reducing illegal immigration."

30. Tellez converted this to a labor displacement figure in May 1992, when he predicted that over 1.4 million farmers and workers would be displaced by 2002 due to freer trade and land reforms. Tellez projected that the farm work force would fall from 26 percent in 1992 (7.l8 of 30 million) to 16 percent by 2002 (6.4 of 40 million). Cited in Cornelius, 1992, p. 6.

31. About $12 billion is transferred outside the U.S. each year by money remitters or transmitters such as First Data Corp's Western Union and Moneygran Payment Services—these two collectively account for $11 billion or 90 percent of the nonbank international transfer market in the U.S. U.S. banks transfer an estimated $800 billion daily overseas. Wall Street Journal, May 20, 1997.

32. Some surveys indicate that employers prefer immigrants because their "right attitude" includes a tendency not to complain about labor law violations. Enforcement experience suggests that a majority of garment and agricultural employers inspected by labor law authorities are violating *some* labor law, but it is often very difficult to quickly prove the violation.

For this reason, labor inspection records indicate that many violations are "technical," such as failing to post safety notices, because such violations are clear, while others take time to prove. For example, it can take hours of investigative time to determine whether workers paid piece rate wages are earning the minimum hourly wage of $4.25 to which they are entitled, and so, rather than go through incomplete records, the inspector may simply issue a citation for a missing poster and move on. For a review of enforcement practices in immigrant labor markets, see Martin 1994.

33. It might be noted that the Fair Labor Standards Law, which established minimum hourly wages, overtime pay, and child labor rules, is routinely violated by some firms. DOL's 800 labor inspectors open 20,000 investigations each year, mostly following complaints, and win settlements for workers in about 90 percent of the cases. One employer group estimates that U.S. workers are unlawfully denied $19 billion per year in overtime pay—federal law requires that workers employed more than eight hours daily or 40 hours weekly be paid 1.5 times their normal wage (G. Pascal Zachary, "Many firms refuse to pay for overtime, employees complain," Wall Street Journal, June 24, 1996).

34. Wiest distinguished between temporary-recurrent migrants who were typically away for less than one year, indefinite migrants who those whom the household members

interviewed say that do not know if the absent member will return, and permanent relocation was the term applied to those who left the village.

35. Taylor (1987) emphasized that illegal migration to the U.S. does not contribute disproportionately to a Mexican household's income.

36. Cornelius concluded that Las Animas may be the exception in the sense that U.S.-bound migrants from there followed well-trod network paths to a few areas of the U.S. Cornelius argued that "social network-based migration does not necessarily tie a Mexican sending community to a single receiving area within the U.S."

37. Donato, Durand, and Massey concluded that IRCA was not deterring illegal entries. The 1987-89 drop in INS apprehensions, they concluded, was probably due to legalization, not to fewer Mexicans migrating to the U.S.

Espenshade agreed with the conclusion that the prospect of being apprehended seemed to do little to discourage Mexicans attempting illegal entry in the late 1980s and early 1990s, but he emphasizes that, once inside the U.S., the probability of apprehension goes down, but the costs of being apprehended goes up, since apprehension inside the U.S. can mean loss of a U.S. job (1994, 886).

Most evidence points to a probability of apprehension on any illegal attempt of about 0.3—about 74 percent of a sample of persons legalized under the general legalization program—and 68 percent of Mexicans—reported that they had never been apprehended by the INS between their entry—which should have been before January 1, 1992, and their application for legalization in 1987-88 (INS, 1992, 15).

Reports in 1995 from the single most labor-intensive activity in North American agriculture—the harvest of about 200,000 acres of raisin grapes around Fresno, California from mid-August to October—found that newly arrived and unauthorized workers were still getting into the U.S. and going to work. The unauthorized workers in the raisin fields reported that they paid higher fees to smugglers in summer 1995, $300-$400 versus $200-$300, but the larger increased cost was the lost days of work in the U.S. because of delays in crossing the border.

Most of the raisin workers, however, persisted until they succeeded in reaching the Fresno area (INS Evaluates Gatekeeper, SouthPAW, Migration News, October 1995).

38. Massey and Espinosa (1995, 51) argued that many Mexican migrants from West Central Mexico in the late 1980s and early 1990s were motivated to migrate to the U.S. to seek capital to invest in Mexico, not simply searching for higher incomes. These migrants could not obtain the capital they needed in Mexico because interest rates were high. However, high interest rates are also typically associated with slow economic growth and joblessness, so that high Mexican interest rates could just as plausibly be associated with more emigration for very traditional low wage and jobless reasons for migration.

39. In a September 10, 1992 speech to the Detroit Economic Club, President Bush said that the economic growth accelerated by NAFTA should "cut down on the cross-border flow of illegals that I think is burdening a lot of our country, particularly California."

40. For those who migrate to the U.S., interviewers asked whether the migrant was legally authorized to work in the U.S., so that persons crossing the border with tourist visas, border crossing cards, or borrowed or false documents were coded as making illegal entries.

U.S. Impacts of Mexican Immigration

Michael J. Greenwood & Marta Tienda[1]

Introduction

An assessment of the impacts of Mexican immigration in the United States depends on how many come, and when (first chapter); who migrates, where they come from and where they settle; how long they stay, how they and their offspring adjust (second chapter); why they come and how they select their U.S. destinations (third chapter). Previous chapters have elaborated the complexity of each of these themes, which bear on the nature and magnitude of demographic, social, and economic impacts of Mexican migration. An assessment of the impacts is further complicated because, in addition to the difficult issues considered in prior chapters, the consequences of Mexican immigration differ over time, across diverse regions, and among various segments of the society and sectors of the economy.

This chapter is concerned with the consequences of recent (largely 1960 to the present) streams of Mexican migrants, although we acknowledge that many current impacts have accumulated over several decades. Impacts deriving from decades of Mexican migration are manifested in multiple spheres of social, political, and economic life. Today these impacts are most clearly evident in locations where the

Mexican-born population is densely settled, notably the cities along the U.S.-Mexico border, and, several large cities in the Southwest (e.g., Los Angeles, San Diego, Houston, Dallas), and Chicago. That many native-born Mexican origin residents are themselves descendants of recent migrants renders the focus on recent entrants arbitrary, yet necessary for policy considerations. We elaborate these issues in the discussion of demographic impacts.

It is important also to acknowledge how changed economic and socio-political circumstances may alter the contemporary impacts of Mexican migration relative to earlier periods. There is extensive empirical evidence that the returns to education have been rising in the United States since the mid-1970s, and this implies more limited economic mobility for recent migrants relative to earlier migrants from Mexico. Taken together, the lowered demand for unskilled workers coupled with a less tolerant climate for welfare and health care benefits have increased the challenges of migrant integration and adaptation while fueling public perceptions that the costs of migration exceed the benefits.[2]

The preponderance of scientific evidence refutes this view, but acknowledges that not all segments of society share equally in the benefits of immigration (Borjas, 1977; Hammermesh, 1997; Smith and Edmonston, 1997). Moreover, the costs are borne disproportionately by certain groups in the United States. Herein resides an important source of misunderstanding about the benefits and costs of migration generally and Mexican migration in particular, namely the distributional aspects of gains and losses. Therefore, we depart from the simple premise migration from Mexico produces benefits to the United States, and that these benefits come at a cost. Accordingly, our main task is to identify the benefits and costs and to specify which groups benefit and lose from Mexican migration.

To decipher benefits and costs deriving from out-migration from Mexico and in-migration to the United States, we lay out a heuristic framework that differentiates national from regional and local impacts and also separates, for analytic convenience, economic from socio-cultural, demographic and political consequences. For most outcomes, the distinctions are largely theoretical because all of these dimensions are highly inter-related. We also acknowledge that short and long-term impacts differ, that some impacts are transmitted intergenerationally, and that many benefits and costs can not be quantified. Although we mainly emphasize measurable impacts, we also consider unmeasured benefits and costs, including those based on perceptions rather than facts, because these also can be highly influential in shaping responses to migration. Our attempt to provide a balanced and nuanced portrait of benefits and costs is crucially important for contemplating policy strategies, whose ultimate goal is to maximize benefits and minimize costs for both countries.

Impacts and the Changing Character of Migration

Migration from Mexico to the United States has changed over time, which suggests that the historical dimensions of the labor flow are important for understanding contemporary impacts. Initially Mexican workers were almost exclusively destined to jobs in the agricultural industry. In this instance, the local costs might be relatively contained, even though the benefits were enjoyed by the entire U.S. population through lower food prices. However, over time, the Mexican flow has changed in size, volume and characteristics (first two chapters, this volume). Even though current migrants from Mexico largely seek urban destinations and find employment outside of agriculture, vestiges of the historical role of Mexican workers in U.S. agriculture remain, as evident in their disproportionate representation in farming industries. We elaborate on these points below.

The highly fluid social, demographic and political contexts in which U.S.-bound Mexican migration has evolved render the task of drawing conclusions about some impacts tentative, although other impacts are amenable to firmer conclusions. For example, we are confident in our inferences (substantiated below) that the magnitude of impacts in the United States are more pronounced in places that send and receive large volumes of migrants. However, we also emphasize that social, economic and demographic impacts are not confined to migrant-sending and receiving areas because local impacts may be arbitraged by secondary migration of people and capital, and by multiplier effects that yield benefits to consumers of less expensive goods produced by migrants. In addition to migration, other channels distribute the economic effects of migration, notably international trade, taxes and transfers.

Two additional features of contemporary Mexican migration are relevant for understanding social, demographic, political and economic impacts in the United States. One is the changing composition of the flows between temporary and permanent migrants. Temporary migrants are themselves highly differentiated in ways that shape their impacts in the United States: some sojourn back and forth throughout their productive lives, while others take a single or a few trips over their life cycle (Massey, et al., 1995). These patterns of migration have different implications for all types of impacts, be they social, economic, demographic, or political. Unfortunately, owing to data limitations, few studies of impacts distinguish between permanent and temporary migrants, except in discussions of highly specialized flows, such as braceros or other temporary seasonal workers.

A second feature of Mexican migration that has important implications for impact assessment concerns the legal status of the migrants. This feature is crucial

because participation by unauthorized workers in social programs and their consumption of tax-financed social services is a highly sensitive political issue undergirding the latest round of restrictions on the access of the foreign born to social welfare benefits (see note 2). Although, it is difficult to distinguish various types of impacts according to legal status, several recent studies have attempted to estimate the fiscal and labor market impacts of documented and undocumented flows. We report on these studies below, and where data permit, refer to the experiences of the legalized population.[3]

Chapter Organization

Our assessment of the myriad impacts of Mexican migration to the United States is based on new syntheses of existing studies as well as several original papers. First, we summarized existing studies about the impacts of Mexican migration to the United States. Because the literature about the impacts of the foreign born in the United States is voluminous, we sought to distinguish, as much as possible, whether and how impacts of Mexican migration differ from those of migration in general.

To preface our evaluation, we first present a typology that frames our discussion of various dimensions of impacts according to level of aggregation, and we discuss the distributional aspects of Mexican migration for understanding local, regional and national impacts. This section is followed by a general overview that describes how Mexican migration to the United States differs from U.S. immigration in general. The purpose is to identify what these differences portend for understanding impacts of Mexican migration in various social domains and areas of the country that receive the largest shares of Mexican migrants. We use the 1990 Census of Population and several additional surveys and published data sources to depict demographic, economic, social and political impacts. All data sources have their limitations, which are discussed in appropriate sections. In striving to present our main findings in nontechnical prose, we have prepared a series of appendices to present technical and tabular materials as well as detailed descriptions of the various data sources used.

Conceptualizing Impacts of U.S.-Bound Mexican Migration

We begin with a heuristic framework that depicts various domains through which Mexican migration impacts receiving communities. Our purpose is two-fold. One is to identify the various domains where impacts of Mexican migration will be identified. Second, the framework serves as a basis for organizing the literature reviews and

presenting findings from prior studies and those prepared specifically for the binational study. We strive for the most balanced accounting possible, but because the nature of the impacts (both benefits and costs) differs in magnitude, kind, and amenability to quantitative analysis, we provide considerable detail and comment on the conclusiveness of the evidence presented in various studies.

Dimensions of Impacts

We define impacts as consequences or changes in social, demographic, economic, cultural or political arrangements that stem directly or indirectly from Mexican migration to the United States. Not all of these impacts are measurable, but for heuristic purposes, it is worthwhile to think broadly about the myriad consequences of such migration. Moreover, the nature and magnitude of impacts manifest themselves differently at national, regional, and local levels, and vary over time, partly because some are cumulative, and partly because migrants (and especially their offspring) assimilate economically and socially in the United States, thereby changing the character and magnitude of impacts inter-temporally and/or inter-generationally.

Levels of aggregation are important because benefits and costs differ accordingly, and because policies governing migration may originate at one level, but may produce various intended and unintended consequences at different levels. Although some impacts measured at the national level may be quantitatively small, at the regional and local levels these same impacts can be very large. Put another way, studies based on specific local labor markets or school districts are more likely to show large effects of Mexican migration than those based on regional or national levels analyses.[4]

Simply stated, most impacts of Mexican migration will be more pronounced in locales and industries where migrants reside and work. For example, the impacts of Mexican migration on U.S. public education outlays are much greater (both in absolute per-capita terms and in relative terms) in Los Angeles than in Fargo, ND, and, as we show below, they also depend on the legal status of the migrants and their children. Average impacts (per capita or relative shares) lose this important distributional dimension, which is crucial for understanding the political hysteria in California leading to Proposition 187 and related initiatives to limit access of migrants to social consumption services and means-tested income transfers. Accordingly, we make every attempt to spell out channels through which impacts are produced and to specify the level of aggregation at which generalizations and specific conclusions obtain.

1. *Demographic impacts* stemming from migration from Mexico manifest themselves through changes in the age structure and gender composition, as well as the

ethnic and racial composition of a population, which can be quite substantial at the local level if migrants leave from or settle in a few selected cities and states, even if the national population composition does not change much. Although Mexican migration also contributes to net U.S. population increase, this "outcome" has not been a major preoccupation of national demographic impact assessments.[5] Rather, population losses and gains are more salient at local levels, where a relatively large influx not only can lead to overcrowding (Myers and Lee, 1996), but also visible changes in race and ethnic population composition.

Beyond these direct demographic impacts (i.e., changes in population composition, density, and natural increase), indirect demographic impacts derive from other migrant characteristics. For instance, the higher fertility of Mexican-born women relative to native-born women of Mexican or other origins have implications for future demographic impacts, and in particular, the size of the Mexican-origin population (Forste and Tienda, 1996; Smith and Edmonston, 1997). However, these effects may be tempered by patterns of intermarriage that not only reduce the numbers who self-identify as Mexican origin, but also may result in lower fertility among assimilated groups (Smith and Edmonston, 1997). Additional indirect demographic impacts of migration may stem from residential mobility of native populations from localities that receive large shares of migrants to those that receive few migrants. Also, native populations can respond by not moving to places where immigrants locate which they might consider in the absence of immigration. However, it is unclear whether concentrated settlements of the foreign born result because natives move out first, creating residential opportunities for the newcomers, or whether the rising migrant composition of a community results in out-migration of native populations. Unfortunately, this question can not be addressed with existing data.

2. *Economic impacts* of Mexican migration to the United States are concerned with quite diverse outcomes. Therefore we distinguish several broad channels of influence through which migration has made an impact on the economy of the receiving society. The dominant and most commonly studied broad channel of influence focuses on the *labor market*, namely the direct effect of migrants on the employment and wages of U.S. residents (both natives and prior migrants). One common view of labor market impacts is that migrants take jobs away from native workers and depress their wage rates. Although this belief is widely shared because it proliferated in the popular media during the 1980s, empirical evidence is mixed, as we elaborate below.

Mexican migrants also influence employment and wages through their demand for goods and services. Moreover, migrant workers can be complements as well as substitutes for native workers, and the net effects of migrants on the wages of natives are also difficult to assess. That migrants also create jobs through their

contributions to production and their own demand for goods and services makes it very difficult to estimate their net employment and wage effects. Industry-specific studies suggest some substitution of migrants for domestic workers, but these studies fail to identify what happens to the displaced workers (Martin and Midgley, 1994:30). Moreover, these studies do not clearly indicate whether the substitution resulted from wage competition (i.e., whether employers pay migrant workers less for comparable work) or whether employers prefer migrants because of other unobserved characteristics, such as attitudes, dependability and willingness to work extra time (Krischenman and Neckerman, 1991; Tienda and Stier, 1996; Tienda, 1989).[6] Neither is it obvious that Mexican migrants have lower reservation wages than equally unskilled domestic workers (Tienda and Stier, 1996).

A second broad channel through which migration to the United States produces economic impacts is the *fiscal channel*. Narrowly defined, fiscal impacts are the current account balance between what migrants pay in taxes and fees, and what they consume in tax-supported amenities and services. Conceived more broadly, fiscal impacts also involve the prices of public goods where immigrants live (e.g., higher taxes due to the increased costs of providing various public services), as well as the quality of services received (e.g., overcrowding in schools). That the majority of Mexican migrants earn low wages is undisputed. Therefore, as a group, they also pay lower than average income taxes. Mexicans who reside in the United States also have larger than average family size, so they may consume proportionately more in public education services than they pay in local taxes. However, many Mexican migrants who move back and forth may pay taxes and not receive equivalent benefits.

Migrant participation in the welfare system has been an issue of considerable concern in recent years. Migrants from Mexico come to the United States in search of employment opportunities and higher wages. Welfare availability does not appear to play a major role in their decisions to enter the United States, and when they are young, their propensity to participate in the welfare system (primarily Aid for Dependent Children or AFDC) is lower than that both of otherwise comparable natives in general and of otherwise comparable native-born persons of Mexican ancestry. However, older persons born in Mexico tend to participate more in SSI than otherwise comparable natives, perhaps in part because those who are 65 and over do not qualify for Social Security, whereas native-born persons do qualify.

The fiscal issue is further complicated by the fact that Mexican (and other) migrants pay Social Security taxes, but many are not eligible for Social Security benefits either because they are too young to collect, because of their legal status, or because they return to Mexico before paying the required number of quarters. However, many receive Supplemental Security Income benefits, which results in another source of income transfers. Finally, costs of migration services also have

risen because tighter border surveillance is expensive. Although these expenditures disproportionately benefit the Southwestern states that share a border with Mexico, they are financed from federal taxes, and therefore the costs are incurred by all citizens. This outlay is seldom considered in assessments of fiscal impacts, perhaps because the outlay also involves opportunity costs that are not easily estimated (e.g., funds that may be spent on welfare, highways, etc.).

Of course, fiscal impacts change over time, depending on (1) changes in the demographic profile of the foreign born population (especially the relative balance of school-age and elderly groups); (2) changes in the economic status of successive cohorts; and (3) future paths of government spending. In general, immigrants are more costly than natives during childhood because school-aged children often require special outlays for bilingual education, but immigrants are usually less expensive in old age. Over a lifetime these differences tend to balance out, but whether costs exceed benefits ultimately depends on future earnings and successful economic adaptation of migrants. Age at arrival is crucial for assessing lifetime earnings: the younger the age at arrival, the more likely that future earnings will offset costs of immigration (Smith and Edmonston, 1997).

A third and less studied broad channel of economic influence focuses on *scale effects*, namely whether the volume of Mexican migration coupled with its high geographic concentration has a positive economic effect. Virtually all of the formal theoretical work on the effects of immigration assumes constant returns to scale, which tends to make the predicted effects less positive than if increasing returns were assumed. As consumers, the foreign born and their offspring expand the domestic market and also encourage increased investment expenditures, thereby augmenting aggregate demand.

Some public goods, such as national defense, do not depend directly on the size of the population (as does education). An increase in population ought not increase the need for national defense, but would increase the number of people paying for defense, thus lowering the cost per capita and lessening the burden on the native residents. On the other hand, Mexico-born and Mexican-ancestry populations have low U.S. military participation rates, which also may deprive them of an important path to occupational mobility. Scale effects associated with migration emerge in highly complex ways, with variable impacts for national, regional and local markets.

3. *Social and political impacts* are perhaps the most difficult to assess partly because it is difficult to classify social and political consequences into costs and benefits. Because most Mexican migrants are integrated into the United States through existing Mexican migrant or Mexican-American neighborhoods, barrios, and settlements, the interaction between the migrants and the wider U.S. citizenry is partly mediated through the existing Mexican-American community. The Mexican-

American community has experienced major changes since 1960: the population became more urban; more educated; and, importantly, more politically active. Another important consideration for understanding social impacts is that levels of residential concentration of contemporary migrants are unprecedented by historical standards (Higham, 1997). Also, the intense inflow of new migrants from Mexico coupled with dense settlement patterns have permitted the proliferation of Spanish in both public and private arenas while slowing the pace of language shift (to English) among the native born (Lopez, 1996).

All the changes summarized above have important implications for discussions about the social and political impacts of Mexican migration in the United States. In particular, it is essential to consider the paradoxical way in which Mexican-American political assimilation in the past 30 years has widened the breach between Mexican migrants and the more settled Mexican-American communities. The breach between migrants and natives has proved to be something of a limiting factor in further Mexican-American political empowerment. If ethnic diversity has been heralded as a major asset of American society, it is also considered a cost, particularly when tied to migration. The migrant origins of the U.S. population are quickly forgotten when negative public perceptions about migrants are fueled by fears that they increase job competition, drive up taxes, and contribute to rising crime rates. Such perceptions, however misguided, can exert powerful influences on the climate of opinion toward migrants, including early and recent arrivals, and trigger prejudice and, under the worst case scenario, ethnic uprisings (Higham, 1997; Smith and Edmonston, 1997).

4. *Other impacts*, our residual category, includes a myriad of consequences ranging from cultural transformation of U.S. neighborhoods and communities to human costs incurred by the migrants stemming from tightened border controls that raise the risk (and consequences) of unauthorized entry and the impoverization generated by new legal restrictions on access to means-tested benefits. Cultural impacts of the sustained migratory streams between Mexico and the U.S. are evident in the proliferation of businesses that cater to ethnic concerns; the proliferation of Spanish-speaking in public places; and the emergence of "sister" communities in the United States which reproduce Mexico's rich cultural variation in the United States.

Theoretical Principles and Their Distributional Implications

Labor migration, whether internal or international, involves three general types of (income) redistributions: (1) from the origin area to the destination area; (2) within the origin area between the various factors of production, usually from other

factors to labor; and (3) within the destination area between the various factors of production, usually from labor to other factors. These effects are seldom symmetrical, but they are crucial for framing binational relationships politically. Moreover, numerous issues arise regarding the assumptions that underlie these three redistributions, such as whether the migrants own capital and bring it with them, or acquire it and take it to their origin countries. Nevertheless, international migration triggers income redistribution, although the specific redistributions depend on who moves between which places.

These redistributions derive from three sources: (1) pecuniary externalities; 2) technological externalities; and (3) the presence of market distortions and public goods. Pecuniary externalities occur through the market as supply and demand changes caused by migration affect relative wages and relative prices. With regard to migration from Mexico to the United States, this type of externality has received the most attention. The workings of the market to a large extent determine how wages and employment opportunities are affected for natives and prior migrants. Such wage and price changes produce income redistribution within both countries. For example, the historical flow of Mexican migrants to jobs in southwestern agriculture redistributed income in favor of land and capital owners.

The redistribution between the countries involves individuals who were productive members of Mexico's labor force becoming productive members of the U.S. labor force. If the migration was motivated by a positive wage differential favoring the U.S.—a wage differential that reflects a labor productivity differential—then the aggregate output of the two nations taken as a whole rises. The migrants themselves clearly benefit, and as long as the migrants have positive marginal products in each nation, Mexico's aggregate output falls whereas that of the United States rises. However, aggregate output or income is probably a less relevant indicator of a nation's economic welfare than per capita income. Whereas per capita income of both nations combined presumably would rise because of migration from Mexico to the United States, that of either nation could fall.

Technological externalities occur through nonmarket mechanisms, and not because of market-induced wage and price changes. These externalities may cause either positive or negative effects in origin and destination areas, but have not played a major role in the debate regarding the effects of Mexican migration to the United States. Many potential technological externalities have been discussed in connection with the education of migrants, especially those migrants who are well-educated relative to the population of the origin society. For example, the "brain-drain" debate questioned whether scientists and engineers trained at public expense in poor countries like India developed technologies at their destinations that were beneficial to the new society. Because migration from Mexico has been primarily from areas where education levels are low (especially by comparison to the U.S. averages),

this issue has not been at the forefront of the debate about the economic consequences of U.S.-bound Mexican migration.

The presence of market distortions and public goods is a third source of income redistributions that result from migration. Market distortions occur when workers are paid less than their private marginal product, due perhaps to monopsonistic hiring practices or discrimination. Moreover, progressive tax and spending policies can create a difference between an individual's net real wage (i.e., actual wage minus any tax payments plus any benefits received that are financed through the general tax system) and his marginal contribution to national product. This net wage, rather than the actual money wage, is relevant for the assessment of the costs and benefits of migration (Usher, 1977).

If migrants are relatively poor, a progressive tax system may induce an adverse impact on the welfare of the native residents. Furthermore, by virtue of their presence, migrants acquire a share of publicly owned property, thereby receiving a wealth transfer. Whether a net transfer actually occurs depends on the migrant's impact on the cost sharing of social overhead capital. Furthermore, because the financing of social capital frequently occurs over many years following actual construction, it is not clear that a transfer exists. If one does exist, it would be offset to some unknown extent because a large fraction of public expenditures is for the provision of public goods and services that do not vary appreciably with the level of immigration (e.g., Simon, 1982; Reder, 1963). Thus, for example, migrants contribute to the cost of public goods such as national defense, reducing the cost to each original resident without reducing the amount of defense provided. A second major aspect of the debate regarding the economic consequences of Mexican migration to the United States focuses on fiscal effects, which we discuss below.

Migrants are the clearest beneficiaries from migration. Presumably, after taking into account the physical and financial risks associated with their northward journey, individuals who migrate expect to improve their economic status in the United States relative to what it was in Mexico. These economic benefits to migrants are largely produced through participation in the labor market. However, beyond workers as beneficiaries from migration, it is difficult to identify other gainers and losers in the two-nation system, because even when gainers and losers can be identified, the gains and losses are hard to measure. Moreover, many normative issues arise regarding the weights that society attaches to particular gains and losses, or more generally, the welfare function that immigration policy seeks to optimize.[7]

Admittedly, it is easier to theorize about the broad range of possible impacts of Mexican migration than to quantify them. This is because some costs are measurable, albeit quite imprecisely, while the vast majority are not measurable at all. Direct benefits of migration are difficult to measure. For example, economic

impacts that are exerted through increases in aggregate demand or expansion of local markets are usually ignored by analysts due to measurement problems. Impacts operating through international trade are seldom addressed separately, except in connection with labor market influences. Social, political and cultural impacts are most difficult to assess, and we treat these influences in less depth than demographic and economic impacts because existing data do not permit much in the way of original analysis, and because available studies about impacts are similarly limited. Our discussion of social and political impacts is largely, although not exclusively, based on evaluations and insights from existing studies. In the remainder of this chapter we summarize what is known about the U.S. demographic, economic, social, political and other impacts of Mexican migration to the United States.

Guidelines for Impact Assessment

Several attributes of the Mexican foreign-born population are directly relevant for understanding the nature and magnitude of demographic, economic and social impacts in the United States. These include the relative and absolute size of recent cohorts, their settlement patterns, the volume of unauthorized entries, as well as socioeconomic characteristics of those admitted (or who manage to enter without inspection). Before reviewing existing evidence and providing new evidence about the demographic, economic and social impacts of Mexican migration to the United States, we briefly discuss the relevance of each of these characteristics for impact assessment.

Changing Volume of Migration

Mexico currently contributes a larger share to the U.S. foreign-born population than any other country—roughly as much as the entire continents of Asia and Europe. During 1994 alone the United States admitted as legal resident aliens 111,398 persons born in Mexico. Between 1989 and 1993, boosted by legalizations under terms of the Immigration Reform and Control Act of 1986, 2.4 million persons of Mexican birth were legally admitted to the United States. The size of the immigrant flow is important for understanding impacts because arguments about scale economies and about magnitudes of impacts derive directly or indirectly from the volume of migrants, depending, of course, on residential patterns, return migration rates, and other social and demographic characteristics, which we discuss below.

Although recent streams are the focus of most impact assessments, it is important to recognize that contemporary impacts also derive from past migration streams. In the decade 1911-1920, 219,000 Mexicans legally immigrated to the U.S. (Bean

and Tienda, 1987). This flow more than doubled during the 1920s, but abated during the 1930s and 1940s, when immigration virtually stopped (except refugees). Migration from Mexico resumed during 1950s (299,000), and has steadily increased, rising to more than a million immigrants during the 1980s. Between 1990 and 1994, over 2 million Mexicans became legal residents of the United States and accounted for about one in three legal admissions during the period (INS, 1997). This unusually large number, at least by comparison to prior decades reflects the large impact of the amnesty program on Mexicans residing in the United States. All Mexicans granted amnesty were supposed to have been continuous residents of the United States since before 1982.

The temporal pattern of the stream is important for an assessment of impacts because earlier migrants will have aged and retired by 1990; hence, profiles of utilization of Social Security and other tax supported programs will be directly affected. Furthermore, more established streams appear to have a built-in momentum which, given current admission criteria, has accelerated the volume of new migrants in more recent decades.

Settlement Patterns
